REVISION

Information contained within Xerox Control Program-Five (CP-V)/TS User's Guide, Publication Number 90 06 92D (dated June 1973) with revised pages labeled 90 16 92D-1(2/74), 90 16 92D-2(10/74), and 90 16 92D-3(5/75) is modified by information contained in revised replacement pages labeled 90 16 92D-4(12/75). Vertical lines in outer margins of pages labeled 90 16 92D-4(12/75) indicate changes in text to reflect the D00 version of CP-V. Vertical lines on other pages indicate changes from a prior revision.

This manual describes how to use the various time-sharing features of CP-V. It presents an introductory subset of the features in a format that allows the user to learn the material by using the features at a terminal as he reads through the manual. A closely related manual, the CP-V Time-Sharing Reference Manual, 90 09 07, is the principal source of information for the time-sharing features of CP-V. It defines the rules for using the Terminal Executive Language and other on-line processors.

Manuals describing other features of CP-V are outlined below:

- The CP-V Batch Reference Manual, 90 17 64, is the principal source of reference information for the batch processing features of CP-V (i.e., job control commands, system procedures, I/O procedures, program loading and execution, debugging aids, and service processors).

- The CP-V Remote Processing Reference Manual, 90 30 26, is the principal source of information about the remote processing features of CP-V. All information about remote processing for all computer personnel (on-line and batch users, system managers, remote site operators, and central site operators) is included in the manual.

- The CP-V Transaction Processing Reference Manual, 90 31 12, provides information about dynamically modifying and querying a central database in a transaction processing environment. The manual is addressed to system managers, database administrators, applications programmers, and computer operators.

- The CP-V System Programming Reference Manual, 90 31 13, describes the CP-V features that are designed to aid the system programmer in the development, maintenance, and modification of the CP-V system.

- The CP-V System Management Reference Manual, 90 16 74, is the principal source of reference information for the system management features of CP-V. It defines the rules for generating a CP-V system (SYSGEN), authorizing users, maintaining user accounting records, maintaining the file system, monitoring system performance, and other related functions.

- The CP-V Operations Reference Manual, 90 16 75, is the principal source of reference information for CP-V computer operators. It defines the rules for operator communication (i.e., key-ins and messages), system start-up and initialization, job and system control, peripheral device handling, recovery and file preservation.

- The CP-V Common Index (90 30 80) is an index to all of the above CP-V manuals.

Information for the language and application processors that operate under CP-V is also described in separate manuals. These manuals are listed on the Related Publications page of this manual.
## Command Syntax Notation

Notation conventions used in command specifications and examples throughout this manual are listed below.

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
</tr>
</thead>
</table>
| lowercase letters | Lowercase letters identify an element that must be replaced with a user-selected value.  
- CRnnd could be entered as CRA03. |
| CAPITAL LETTERS | Capital letters must be entered as shown for input, and will be printed as shown in output.  
- DPnnd means "enter DP followed by the values for nnd". |
| [] | An element inside brackets is optional. Several elements placed one under the other inside a pair of brackets means that the user may select any one or none of those elements.  
- [KEYM] means the term "KEYM" may be entered. |
| {} | Elements placed one under the other inside a pair of braces identify a required choice.  
- {id} means that either the letter A or the value of id must be entered. |
| ... | The horizontal ellipsis indicates that a previous bracketed element may be repeated, or that elements have been omitted.  
- name[name]... means that one or more name values may be entered, with a comma inserted between each name value. |
| : | The vertical ellipsis indicates that commands or instructions have been omitted.  
- MASK 2 DATA, 2 X'1EF' : BYTE DATA, 3 BA(L(59)) means that there are one or more statements omitted between the two DATA directives. |
| Numbers and special characters | Numbers that appear on the line (i.e., not subscripts), special symbols, and punctuation marks other than dotted lines, brackets, braces, and underlines appear as shown in output messages and must be entered as shown when input.  
- (value) means that the proper value must be entered enclosed in parentheses; e.g., (234). |
| Subscripts | Subscripts indicate a first, second, etc., representation of a parameter that has a different value for each occurrence.  
- sysid1,sysid2,sysid3 means that three successive values for sysid should be entered, separated by commas. |
| Superscripts | Superscripts indicate shift keys to be used in combination with terminal keys. c is control shift, and s is case shift.  
- Lcs means press the control and case shift (CONTROL and SHIFT) and the L key. |
| Underscore | All terminal output is underscored; terminal input is not.  
- IEDIT @ means that, after typing EDIT, a carriage return character has been sent. |
| ☐ ☐ ☐ | These symbols indicate that an ESC (@), carriage return (©), or line feed (©) character has been sent.  
- IEDIT © means that, after typing EDIT, a carriage return character has been sent. |
1. INTRODUCTION

CONTROL PROGRAM-FIVE

Control Program-Five (CP-V) is a general purpose system that operates on a Sigma 6, 7, 9 or Xerox 560 computer and a variety of peripheral devices. CP-V provides for five concurrent modes of operation:

- Time-sharing.
- Multiprogrammed batch processing.
- Remote processing.
- Real-time.
- Transaction processing

SCOPE OF THIS MANUAL

This manual is designed as a basic guide for using CP-V in the time-sharing mode only. It is not intended as a guide to "sophisticated" usage, nor as a complete reference to TEL and other processors. Please refer to CP-V/TS Reference Manual, 90 09 07, and applicable language reference manuals for complete command formats and descriptions. However, Appendix A of this manual presents a summary of TEL commands in reference format.

The command formats shown in the text are not necessarily complete, as for example in the case of PCL COPY. Only the more commonly used forms are given and explained. Also, knowledge of the programming languages available under CP-V is required for full understanding of this manual.

The examples throughout this manual are written for Teletype® terminals (see Figure 1 for layout of a typical keyboard). 2741 terminal users should read Appendix F, "Use of the 2741 Terminal", before reading further in the manual.

TERMINAL EXECUTIVE LANGUAGE

The Terminal Executive Language (TEL) is the on-line command language for CP-V, a concise natural language for performing on-line functions and calling on-line processors. It also provides information services, such as accounting charges and status of available system resources.

Some of the functions performed as the result of TEL commands are:

- Building a file.
- Initiating a processor.
- Loading and executing a program.
- Quitting or continuing an interrupted processor.
- Copying a file.
- Deleting a file.
- Controlling output.
- Setting DCB assignments.
- Submitting batch jobs.
- Checking the status of batch jobs.
- Saving and restoring files.
- Queuing output for symbiont devices.

© Registered trademark of the Teletype Corporation.
• Setting tab stops for terminal I/O.
• Controlling the terminal interface (e.g., page width and length).
• Setting the log-on password.
• Communicating with the operator.

On-line processors available to the user through TEL include

<table>
<thead>
<tr>
<th>Processor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COBOL</td>
<td>ANS COBOL.</td>
</tr>
<tr>
<td>FORT4</td>
<td>Extended version of FORTRAN IV.</td>
</tr>
<tr>
<td>META</td>
<td>Assembler with powerful procedure (macro) capability: Meta-Symbol.</td>
</tr>
<tr>
<td>AP</td>
<td>Assembler which permits programs to be written in segments and to contain command and function procedures.</td>
</tr>
<tr>
<td>BASIC</td>
<td>Processor for creating, executing, and maintaining programs written in a simple mathematical language.</td>
</tr>
<tr>
<td>APL</td>
<td>Processor for interactive problem solving with a minimum of programming effort.</td>
</tr>
<tr>
<td>FLAG</td>
<td>Fast &quot;load and go&quot; FORTRAN compiler.</td>
</tr>
<tr>
<td>Edit</td>
<td>Line/text editor.</td>
</tr>
<tr>
<td>PCL</td>
<td>Language for copying and deleting files, listing directories, and manipulating tapes.</td>
</tr>
<tr>
<td>Delta</td>
<td>Debugging processor used primarily for assembly-language programs.</td>
</tr>
<tr>
<td>FDP</td>
<td>Debugging package for FORTRAN programs.</td>
</tr>
<tr>
<td>COBOL On-Line Debugger</td>
<td>Debugging package for COBOL programs.</td>
</tr>
<tr>
<td>Link</td>
<td>Processor that constructs an executable program (load module) from object-program modules.</td>
</tr>
<tr>
<td>LYNX</td>
<td>Processor that combines the capabilities of Link and the batch load processor.</td>
</tr>
<tr>
<td>Batch</td>
<td>Processor that submits a batch job file to the batch job stream.</td>
</tr>
<tr>
<td>Show</td>
<td>Processor that displays the user's system parameters.</td>
</tr>
</tbody>
</table>

Processors are usually called explicitly by name but may also be called implicitly by certain TEL commands. For example:

<table>
<thead>
<tr>
<th>Processor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUILD</td>
<td>Calls Edit to build a file.</td>
</tr>
<tr>
<td>COPY</td>
<td>Calls PCL to copy files.</td>
</tr>
<tr>
<td>RUN</td>
<td>Calls Link to link a program and causes the program to be loaded and executed.</td>
</tr>
</tbody>
</table>

When a processor is called in this manner, control returns to TEL (rather than to the called processor) immediately after execution of the command.
Figure 1. Teletype Keyboard

1 These keys are missing on some models.
2 This key is positioned elsewhere on some models.
3 This is interpreted as | (OR) on Model 7015.
4 This is interpreted as ~ (NOT) on Model 7015.
2. LOGGING ON AND OFF

DIALING THE COMPUTER

To establish connection with the computer, proceed as follows:

1. Turn on power switch for terminal and for acoustical coupler (or "modem"), as necessary.

2. Pick up telephone handset, wait for dial tone, and dial computer. A high-pitched tone will be heard if a communication line is available.

3. Place handset on acoustic coupler (see Figure 2).

TEL (Terminal Executive Language) now responds with the following message:

XEROX CP-V AT YOUR SERVICE

ON AT (time and date)

LOGON PLEASE:

You can now log onto the system (provided you have been enrolled on the system by the system manager).

LOGGING ON AND OFF

To log on, you must have an account number, a name, and possibly a password. The account is your billing number and the name is your personal or group identification. Both are assigned by the system manager. Password is an account-protection feature that is assigned either by the system manager or by yourself (see PASSWORD Command, below). It can be modified periodically for security purposes.

Upon receipt of the message LOGON PLEASE:, enter your account, name, and password, in that order, separated by commas. The password and preceding comma are omitted if no password has been assigned.

Figure 2. Typical Dialing Unit
Account number and password may each be from one to eight characters in length. The name may consist of one to 12 characters. None of the following characters may be used in the user name, account, or password:

1, ; < > , / = ?

and all control characters acted upon by the COCo.

The graphic representation of certain special characters, such as the left arrow, is terminal-device dependent, as is the availability of the lowercase alphabets. The character set shown above should be regarded as representative only in this respect.

For terminals operated in indirect printing mode, character echoing by the system is normally on but can be turned off (e.g., to suppress printing of passwords or other security-related information) by striking the @ E keys. Striking the @ E keys a second time turns echoing back on. For terminal units operated in direct printing mode, character echoing by the system must be turned off, as above, to suppress duplicate printing of characters.

It may not always be possible to log on. If an error prevents the reading of the logon file, the message UNRECOVERABLE I/O ON RAD, or ABNORMAL ERROR ON LOGON FILE will be typed. Whenever you are unable to log on, start over by striking the BREAK key and try again. The system tries five times to log you on before dismissing you.

If a MAILBOX file (a message file) exists at log-on time, the message CHECK DC/MAILBOX will appear. You may examine this MAILBOX file by copying it to your terminal as follows:

1 COPY MAILBOX @

(The underscored exclamation mark is the "prompt character" issued by TEL.)

Example 1. Logging On and Off.

<table>
<thead>
<tr>
<th>XEROX CP-V AT YOUR SERVICE</th>
<th>The user dials the computer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON AT 12:30 MAR 12, '75</td>
<td>The system identifies itself, states the time and date, and requests that the user log on.</td>
</tr>
<tr>
<td>LOGON PLEASE: 2232,HALL @</td>
<td>In response, the user types in his account number (2232) and name (HALL). He does not use a password because the system manager has not assigned him one.</td>
</tr>
<tr>
<td>12:30 03/12/75 2232 15-9 [1]</td>
<td>A page heading is printed by the system; the items of information in the heading are, in order: time, date, account number, two internal identifiers, and page number (enclosed in square brackets).</td>
</tr>
<tr>
<td>1 O F F @</td>
<td>The Terminal Executive types its prompt character (1) indicating that the system is ready to process a TEL command. Since this was just an experiment for the user, he logs off.</td>
</tr>
<tr>
<td>CPU = .0124 CON = :01 INT = 2 CHG = 10</td>
<td>Summary of accounting information for session.</td>
</tr>
</tbody>
</table>

In Example 1, the user used .0124 minutes of central processor time (CPU = .0124); he was connected to the terminal (from dialing up to end of accounting summary) .01 hour (CON = :01); he interacted with the system twice (INT = 2), logging on and the OFF command. His charge was 10 charge units, an installation-dependent value.
Example 2. Logging On with a Wrong Account Number

XEROX CP-V AT YOUR SERVICE
ON AT 02:30 MAR 12, '75
LOGON PLEASE: 223L,HALL ☞
ACCOUNT/ID 223L/HALL ?
LOGON PLEASE: 2232,HALL ☞

The user dials the computer.
He types in the right name but the wrong account number.
The system questions the incorrect account number, and
asks the user to log on again, which he does.

He then logs off.

Example 3. Inability to Log On Due to Error in Logon File

XEROX CP-V AT YOUR SERVICE
ON AT 12:42 MAR 17, '75
LOGON PLEASE: C37-105,HALL ☞

The user tries to log on.

ABNORMAL ERROR ON LOGON FILE
SORRY, UNABLE TO LOG YOU ON

The system cannot log him on and so informs him.

CPU = .0024 CON = :01 INT = 1 CHG = 10

The accounting summary is presented.

XEROX CP-V AT YOUR SERVICE

The system repeats its logon sequence.

ON AT 12:43 MAR 17, '75
LOGON PLEASE: C37-105,HALL ☞

This time the user's logon is accepted.

He now logs off.

CPU = .0024 CON = :01 INT = 2 CHG = 15

PASSWORD COMMAND

The purpose of the logon password is to protect your resources and files by preventing illicit use of your name and account number. The PASSWORD command allows you to change your password frequently to make it difficult for
anyone else to know what it is. You can also use the command to cancel your password if you wish. The format of the command is

```
PASSWORD, old-password, new-password
```

where old-password is the current password associated with the user and new-password is the password to be associated with the user’s name and account. To assign a password when none exists already, the format of the command is

```
PASSWORD,, new-password
```

To cancel the current password, the command format is

```
PASSWORD, old-password,
```

It is important to remember your password because only the system manager is able to establish a new password when the old one is forgotten.

Example 4. Setting a Password

```
XEROX CP-V AT YOUR SERVICE
ON AT 12:49 MAR 17, '75
LOGON PLEASE: 2232,HALL ☞

The user logs on, with no password set.

;PASSWORD,,SECRET ☞
PASSWORD CHANGE SUCCESSFUL

The Terminal Executive types its prompt character (;! indicating it is ready to process a TEL command. The user sets his password to SECRET and must now use it whenever logging on until he or the system manager changes it.

-page heading-

OFF ☞

The Terminal Executive types its prompt character and the user logs off. Password SECRET remains set.

-accounting summary-

Example 5. Logging On with Password and then Cancelling Password

```
XEROX CP-V AT YOUR SERVICE
ON AT 14:45 MAR 17, '75
LOGON PLEASE: 2232,HALL ☞

The user logs on but forgets to use his new password.

PASSWORD ?

The system indicates that the password was not entered.

LOGON PLEASE: 2232,HALL,SECRET ☞

The user logs on with an incorrect password.

PASSWORD SECRET?

The system indicates that the password is invalid.
LOGON PLEASE: 2232,HALL,SECRET

The user now logs on with the correct password.

- page heading -

PASSWORD,SECRET.

He cancels his password by typing the PASSWORD with the old password and the required commas.

PASSWORD CHANGE SUCCESSFUL

He then logs off. Next time he logs on, no password will be required.

-accounting summary-

Example 6. Setting a Password and Suppressing Its Printing

XEROX CP-V AT YOUR SERVICE
ON AT 09:05 MAR 20, '75
LOGON PLEASE: 2232,HALL

The user logs on.

- page heading -

PASSWORD E E

The Terminal Executive types its prompt character (1) indicating it is ready to process a TEL command. The user sets his password with the remainder of the PASSWORD command but suppresses its printing by typing @E before the old-password (the first E is not actually echoed), then turns echoing on again. He must now use the password he has just set whenever logging on, until he or the system manager changes it. Any sequence of 1-8 permissible characters may be used as a password.

PASSWORD CHANGE SUCCESSFUL

The Terminal Executive types its prompt character indicating it is again ready for a TEL command. The user logs off. The next time he logs on, he must use the password just set.

-accounting summary -
3. TERMINAL INTERFACE

INTRODUCTION

This chapter describes methods for correcting, modifying, and deleting terminal input and the use of the TERMINAL, PLATEN, and TABS commands.

EDITING OF TERMINAL INPUT

A line of terminal input may be corrected, modified, or deleted, before the line is released to the system (with @). This may be done by way of either character or line deletion:

1. Editing by Character Deletion: On detecting a typing error within a few characters of the point of error, you may delete the last characters typed by typing a corresponding number of rubout @ characters (echoed with a \ character), and continuing the line from the (deleted) point of error. (Any n successive @ characters effectively delete the n successive characters immediately preceding the first @ character.)

2. Editing by Line Deletion: To delete a complete line of input — before giving a carriage return, strike the ESCAPE and X keys or simultaneously depress the CONTROL and X keys (@X or Xc in conventional notation). The system responds with a — (left arrow), effectively deletes the line, gives a carriage-return/line-feed, and positions the carriage to the beginning of input. (The previous prompt character, if any, is not repeated.) The input can then be repeated in correct form. The Xc command will delete not only the current input line, but all lines typed ahead and all pending output.

These editing features apply to any untransmitted line of terminal input, under TEL or any other processor except Delta.

Example 7. Making Corrections to TEL Commands

```
XEROX CP-V AT YOUR SERVICE
ON AT 15:30 MAR 22, '71
LOGON PLEASE: 2232,HALK\L @)

While logging on, the user hits a K instead of an L. To delete K, he strikes the rubout key which echoes back to the terminal as a backslash. Then he types L and completes the logon sequence. (Note that the characters printed at the terminal are those echoed back to the terminal and are not necessarily the same ones typed, as for example \ for @.)

- page heading -

1Q PASSWORD Y07 Xc @

The user then types in a password command but notices an error (password misspelled) before striking the carriage return key. Instead he depresses CONTROL and X simultaneously, which the system echoes back as a left arrow (or possibly an underline). This causes the line to be cancelled and a carriage return.

PASTWO\\SWORD Y07 @

PASSWORD CHANGE SUCCESSFUL

The user notices still another error. This time he deletes three characters and then completes the command successfully. Note that prompt character (1) is not repeated.

1OFF @

He then logs off.

- accounting summary -
```
TERMINAL COMMAND

The TERMINAL command is used to inform the system of the type of terminal used, and is required only if the terminal differs from a type of terminal unit specified as standard by the system. (This information can be obtained from the installation manager.)

Format:

    TERMINAL type[algorithm]

where

type specifies the terminal type and may be any type from the list below:

<table>
<thead>
<tr>
<th>Type</th>
<th>Translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33</td>
<td>Teletype Model 33</td>
</tr>
<tr>
<td>35</td>
<td>Teletype Model 35</td>
</tr>
<tr>
<td>37</td>
<td>Teletype Model 37</td>
</tr>
<tr>
<td>7015</td>
<td>Xerox 7015 Keyboard Printer</td>
</tr>
<tr>
<td>DATA</td>
<td>Teletype Model 33</td>
</tr>
<tr>
<td>EAPL</td>
<td>IBM 2741 EBCD APL</td>
</tr>
<tr>
<td>ESTD</td>
<td>IBM 2741 EBCD Standard</td>
</tr>
<tr>

```
PLATEN COMMAND

The PLATEN command can be used to change the page width and/or page length for terminal input and output. The format of the command is:

\[ \text{PLATEN} [w] [l] \]

where

- \( w \) is the maximum number of characters to be written per line on the terminal. If more than \( w \) characters are written, a line feed and carriage return character sequence is inserted to break up the output into segments no longer than specified by \( w \). If \( w \) is 11 or less, no line feed and carriage return sequence is supplied. In this case, the width of the line is limited only by the physical constraints of the device on which the line is produced (up to a maximum of 140 characters). If the \( w \) field is omitted, the current width setting is retained.

- \( l \) is the number of lines per page of terminal output (exclusive of the header) and must be within the range 0-255. If the \( l \) field is omitted, then the number of lines per page remains unchanged. If \( l \) is set to 11 or less, no heading is produced and the page length is unlimited. Note that a heading occupies 11 lines.
The default case when a user logs on is equivalent to PLATEN 0,0. This means that no line feed and carriage return sequence is supplied, that no heading is produced, and that the page length is unlimited.

Example 9 shows how PLATEN can be used to change page width. The example contains four job steps, i.e., major functions during a session that cause the invoking of processors such as EDIT, PCL, or META.

Example 9. Using PLATEN Command to Change Page Width

```
XEROX CP-V AT YOUR SERVICE
ON AT 17:24 APR 15,'71
LOGON PLEASE: HALL

17:24 04/15/71 14777 23-7 [1]

!BUILD TEST1 @)

1.000 1234567890123456789012345678901234567890 @)
2.000 @)

The user enters the BUILD command to build file TEST1. File building is described in detail in Chapter 4. (This is the first job step of the session.) The @) alone on line 2.000 terminates the build operation and control returns to TEL.

!PLATEN 20 @)

The page width is set to 20.

!COPY TEST1 TO ME @)
12345678901234567890
12345678901234567890

File TEST1 is printed at the terminal. The page width is now 20. (The COPY command, which implicitly invokes the PCL processor, is the second job step.)

!PLATEN 39 @)

The page width is set to 39.

!COPY TEST1 @)
1234567890123456789012345678901234567890

File TEST1 is printed again but with 39 characters per line. (This COPY constitutes a third job step. Note that the output specification TO ME is omitted. PCL assumes ME as a destination device by default.)

!PLATEN 12 @)

The page width is set to 12.

!COPY TEST1 @)
12345678901234567890
345678901234
567890123456
7890

File TEST1 is printed again but now has 12 characters per line. (This is the fourth and last job step.)

!OFF @)

The user logs off. Note that the last PLATEN command is still in effect. (However, the page width and length is always set to the default case, equivalent to PLATEN 0,0, when a user logs on.)
```

CPU = .0097
CON= :03 INT
= 13 CHG =
= 42

Editing of Terminal Input 11
Example 10 shows how PLATEN is used to change page length. (This example also contains four job steps.) Note that the page-length specification refers to the number of single-spaced lines in the body of the page, i.e., excluding top-of-page heading and spacing. Each line of double-spaced output, where double spacing occurs, counts as two lines. Therefore, if \( n \) double-spaced print lines are desired, the page-length must be specified as \( nx2 \). Occasionally, only \( \leq n-1 \) lines, or less, will be printed due to various circumstances, e.g., an intervening single-spaced command line.

Example 10. Using PLATEN Command to Change Page Length

 14.000 14 @)
 15.000 15 @)
 16.000 @)

The user builds file TEST2. (The @) alone on line 16.000 terminates the build operation and control returns to TEL.)

PLATEN 72,12 @)

The PLATEN command sets page width to 72 characters and the length to 12 lines.

17:30 04/15/71 14777 HALL 21-9[2]

The system prints the second page heading, on overflow of newly set page length.

COPY TEST2 TO ME @)

A copy of file TEST2 is printed at the terminal.

17:31 04/15/71 14777 21-9[3]

The third page heading prints.
```
The 12-line page is still in effect.

CPU=.0129 CON=:05 INT = 19 CHG = 55

**TABS COMMAND**

The TABS command is used to simulate typewriter-like tab stops for terminal input and output. TABS supplies the tab-setting values that are to be used by the system when it encounters a 'tab character' in the input or output line.

You can then tabulate by typing $\text{I}^{\text{C}}$ (CONTROL and I), or $\text{I}^{\text{E}}$ (ESCAPE followed by I), in your input wherever you desire a tab in both the input and corresponding output. However, in order to cause tab characters to be inserted whenever the $\text{I}^{\text{C}}$ or $\text{I}^{\text{E}}$ sequence is typed, the space-insertion mode must be turned off by typing $\text{E}^{\text{S}}$ (ESCAPE followed by S).

The tab settings can be changed by another TABS command. Tab simulation can also be turned off, and then back on, with the key sequence $\text{E}^{\text{T}}$.

**Example 11. Using the TABS Command**

```
XEROX CP-V AT YOUR SERVICE
ON AT 17:35 APR 15,'71
LOGON PLEASE: 14777, HALL @
- page heading -
\tabs 8,22,37,45,52 @

The user sets tab-stop values for terminal input and output.

\es \@

Space insertion mode is turned off.

\build test3 @

1.000 THIS@example illustrates use of tabs
2.000 @

File TEST3 is built using tabulation ($\text{=} \text{I}^{\text{C}}$ or $\text{I}^{\text{E}}$).

\copy test3 @

This example illustrates use of tabs

This file is printed with tab simulation on.

\et @

The user now turns off tab simulation with the sequence $\text{E}^{\text{T}}$.
```
This example illustrates use of tabs.

The file now prints with no tabbing. Note that single spaces are inserted in place of tab characters.

- accounting summary -
4. MANIPULATING FILES

FILES IN CP-V

Almost from the moment you become a user, you start accumulating data—the information upon which the system must operate to provide the answers to the problems you pose. All of the processors mentioned in Chapter 1 produce some kind of data; for example:

- **Edit** allows you to create the collection of statements necessary to phrase a problem-solving procedure in the language of an assembler or compiler, called a source program, and to create input data for such programs.
- **BASIC, FORTRAN, and META** allow you to translate a source program, which is only a model of the external idea, into a form suitable for execution by the machine. This translation produces **object code** as the result of either a "compilation" or "assembly" process.
- **LINK** prepares the relocatable object code for machine execution, in the form of a load module.

These different kinds of data have at least one characteristic in common: each must be stored in some retrievable form, both between the steps of an information-processing operation, and between executions of the same operation.

Conventional batch systems provide the user with several ways of storing data, principally on punched cards or magnetic tape. Although these media provide low cost, long-term storage, they require operator intervention at the central computer site when the stored information is to be accessed or updated. This intervention may be merely inconvenient for batch operation when the information is used frequently, but it is generally infeasible for on-line use of a time-sharing system.

The system's file-management capabilities provide an alternative and remarkably versatile medium for maintaining your working data—a medium which greatly lessens your dependence on conventional external forms of storage, and increases the flexibility with which the data can be manipulated. File storage is implemented through use of the Xerox Rapid Access Data Storage System (RAD) and/or through use of public disk packs. Generally speaking, a RAD is a nonremovable rotating-disk memory device containing approximately 6 million characters (or bytes) of storage, any portion of which can be accessed within a very short time. Public disk packs provide approximately 24 million characters of storage. (The system allows you, the on-line user, to access conventional peripheral-storage devices and private disk packs also, if you are so authorized.)

The Monitor, through its file-management system, allows information to be stored on RAD and/or disk packs and identified symbolically, simply by a file name chosen by the user. The files are segregated by account number (your identifying number assigned by the installation manager). Therefore, you cannot inadvertently generate file names that conflict with those of other users outside your account. Certain other information about the file, such as restrictions on access by other users, is also kept with the file.

Files can be used to store any kind of information. They can contain source-language programs built with Edit or BASIC, translated source programs produced by a compiler (relocatable object code), or object code in executable form (a load module) produced by the link-loader. They can also contain collections of alphanumeric data, and natural-language text.

A file is identified by a name of 1–10 characters constructed from a prescribed set of characters. (Some processors, such as Edit, allow up to 31-character file names for special purposes.) The permissible character set contains all of the alphabetic and numeric characters plus most of the commonly used special symbols. Typically, you will need no more than the alphabetic and numeric characters. In the command-language formats given throughout this manual, the symbol most commonly used to indicate a "file name" is fid, which stands for file-identification. A file-identification actually can include an explicit account number and password, as well as the file name. But in our examples, and in most actual usage, fid is interpreted simply as a file name. Complete rules for the structure of file-identifications are given in Appendix B.

Having created a file of information, you are completely free to access or delete it, replace it, or modify it, through on-line services, without any operator intervention. A general rule is that you may not delete or modify files not in your account, though often you may access such files.
Sometimes files are created automatically for you by the system. It is possible to call a processor such as FORTRAN to translate a source program without specifying a file in which to store the object code. In this case, the system creates a unique temporary file, associated with your account, for output storage. You may refer to this file with the single character $ under certain subsystems. The $ file is temporary in the sense that when you log off, the file is automatically released. This is useful when creating test programs where nothing of permanent value is being created as output.

Any file that is explicitly named for output is permanent, i.e., retained in the file-management system across the periods between on-line sessions. All files explicitly created with BUILD and COPY commands are also permanent. Permanent-file content is maintained and updated solely by the user. However, file storage space is a chargeable resource, and it is in your interest to delete unneeded files whenever possible.

When working with files, there are two command modifiers of importance: ON and OVER. ON implies that the named file does not yet exist. If such a file does indeed exist and ON is used, an error message is sent to the user. (In general, the word TO may be substituted for ON, with the same effect.) OVER implies that the file may exist already and, if so, is to be reused for the new operation. Using OVER also results in a completely new version of the file; any old data in the file is lost. If the file does not exist and OVER is specified, no error is noted, and the file is automatically created. There is no limit to the number of operations that may be performed OVER a file.

Information about the immediate intended use of a file is called a file specification. These specifications are made implicitly by the use of several commands, particularly COMMENT, LIST, and OUTPUT. An explicit specification can be made by the use of the SET command. (See Chapter 10, "DCB Assignments".) For our present purposes, file specifications may be considered to indicate that a file is an input or an output file, and if an output file, what type(s) of output the particular file is to receive.

Once a file specification has been made, it remains in effect throughout a terminal session until changed or deleted by another specification – the one exception concerns source-input files (operational label SI), which always default to the user's terminal at each job step. If, for example, listing output is directed to the file "DATA", then all listing output generated by a series of assemblies or compilations are placed on this file, one behind the other. This convention is known as "file extension" and is automatically in effect for output operations on standard system-assigned files – or more precisely, through certain system-created Data Control Blocks (DCBs). (DCBs are described in the CP-V/BP Reference Manual, 90 17 64, and discussed further in the TEL chapter of the CP-V/TS Reference Manual, 90 09 07.) References to DCBs are gradually introduced further along in this manual, and they are treated specifically in Chapter 10, "DCB Assignments".

File extension is an important feature to keep in mind when operating at the terminal, especially when it is not desirable to stack any output during multiple-job-step operations. File extension is reset to the beginning of the file upon any new specification, even if the specification refers to an already existent file. For example:

```
!LIST ON GRUNCH
!OUTPUT ON RUNFILE
!META SOURCE
!META ME
!META TESTY
```

Listing output directed to file GRUNCH.
Object-code output directed to file RUNFILE.
Read input-file and assemble (job step 1).
Assemble from terminal (job step 2).
Read input-file and assemble (job step 3).

This sequence of commands results in all output being stacked on their respective files, GRUNCH or RUNFILE.

The new listing-output specification and further job step

```
!LIST OVER GRUNCH
!META
```

has the effect of replacing the old contents of GRUNCH with the new assembly listing as the source input is entered from the user's terminal. The object-code output would still be stacked at the end of file RUNFILE. This basic use of file extension logic applies independent of the manner in which file specifications are made, i.e., through the SET command or through commands implying a specification.
To understand certain error comments you may encounter, you will need some knowledge of file organization. This refers to the way the file's contents, i.e., its individual records, are ordered. Three possible organizations are:

- **Consecutive**, where the records can be accessed in sequential order only.
- **Keyed**, where the records may be accessed directly (randomly) or sequentially.
- **Random**, where the file is simply a collection of contiguous storage.

Files built with the Edit processor, having a line number associated with each record (line), are an example of a kind of keyed file. Most files you will use will probably be keyed, but you may see a system comment stating "...file not keyed...". Certain processors are not keyed-file oriented, e.g., BASIC and PCL, though they handle keyed files properly in most cases. Later we indicate what you can do in other cases.

**EDIT**

The Edit processor is a general-purpose, line-number oriented text editor. It may be used to create or modify source programs, data files, reports, etc. for other CP-V processors, specifically for the FORTRAN, Meta-Symbol, BASIC, COBOL, and BATCH processors.

Edit provides file editing capability, i.e., the ability to build, delete, copy, or merge files; to edit within a line of a file; and to do a complex editing operation on each line in a specified range of lines.

The examples in this section illustrate how Edit is used to perform file editing, and to access a file and perform record (line) editing functions such as displaying (TY), inserting (IN), and deleting (DE).

One example of intrarecord, or multiline editing is also given, as a basis for general use of the intrarecord-command group. Edit commands not covered here are described in the CP-V/TS Reference Manual, 90 09 07.

In the command descriptions that follow, the word "line" refers to a line typed by the user; the word "record" refers to a line that has already been transmitted to the system and exists on some file. Thus, we can say "...the line numbered n replaces any identically numbered record..." (i.e., already on the file) without ambiguity. The examples are intended to illustrate usage of the various commands and do not necessarily show the most appropriate way of dealing with a particular kind of file content. More appropriate means may become apparent in later chapters, especially in regard to manipulation of BASIC program text.

**HOW EDIT WORKS**

Edit is a line-number oriented editor in that it automatically associates a line-sequence number with each line of a file built under Edit. All record and intrarecord editing is performed with reference to these sequence numbers. That is, one or more sequence numbers must be specified for record and intrarecord editing commands and also in certain usages of the file editing commands.

To edit a file that does not have sequence numbers associated with it (e.g., a file built under BASIC or under certain batch-mode facilities), you can add the numbers by copying the file with "resequencing" (see Example Copy and Resequence).

Edit prompts with an asterisk (*) character to indicate that it is ready to accept a command. For file-building or line-insertion input, it prompts with a sequence number.

**FILE EDITING COMMANDS**

All file editing commands explicitly name one or more files. The Edit and TEL/Edit commands at the file-editing level are:

- **_EDIT [fid]**
  
  Calls the Edit processor and optionally names a file to be edited, at TEL level (*).

- **_*EDIT fid**

  Names a file to be edited, at Edit processor level (*).
- **BUILD** fid[, n]
  Calls Edit and names a file to be built at the TEL level (1).

- **BUILD** fid[, n]
  Names a file to be built at the Edit processor level (*). The optional number (n) specifies the sequence number with which the file is to begin. If not specified, 1 is assumed by Edit.

- **COPY** fid₁ \[TO⁺\] OVER \ fid₂ \[n\]
  Copies contents of fid₁ either ON a new file or OVER an existing file, fid₂; and, optionally, resequences (i.e., renumbers) fid₂ starting with sequence-number n. COPY can also be used to produce a sequence-numbered (keyed) version of an unkeyed file, in which case n must be specified.

- **DELETE** fid
  Deletes the named file from the system.

- **MERGE** fid₁ \[n₁-n₂\] INTO fid₂ \ n₃-n₄
  Replaces records n₃ through n₄ of fid₂ with the contents of (or record n₁ through n₂ of) fid₁; the merged records — from fid₁ — are renumbered in fid₂ starting with sequence-number n₃. Note: If fid₂ does not already exist, the specified records on fid₁ are copied to the new file and numbered starting with n₃ (i.e., a "selective copy" operation is performed).

- **END**
  Terminates execution of Edit and returns control to the system (TEL) level.

**RECORD EDITING COMMANDS**

To use any of the record or intrarecord editing commands, the applicable file must first be specified with an EDIT-fid command either at the TEL or the Edit level. None of the record and intrarecord-level commands themselves can specify a file.

A useful record-editing command is **TY** — Type Record(s), Including Sequence Number — which displays one, several, or all of the records in a file:

**TY** n₁[-n₂]

where

- n₁ is the sequence number of the first or only line to be typed.
- n₂ is the optional ending sequence number of a range of lines to be typed.

More record-editing commands are described following the next example.

---

**Example 12. Using EDIT to Build and Display a Source File**

In this example, the user builds a BASIC program file, copies it to another file, displays the copy, and deletes the original file.
The user wants to create a file called PRIME. Edit is called implicitly.

```
1.000 10 REM GENERATE PRIMES GR THAN 3
    EDIT prompts for input by printing 1.000. The user types the first line, then types lines 2-10 in response to more prompts by Edit.
2.000 20 P=1
3.000 30 P=P+4, S=0
4.000 40 FOR I = 5 TO SQR(P) + 1 STEP 2
5.000 50 Q=INT(P/I)
6.000 60 IF Q*I=P THEN 80
7.000 70 PRINT P",TAB(0)
8.000 80 IF S=1 THEN 30
9.000 90 S=1, P=P+2
10.000 100 GOTO 40
```

The user types a carriage return immediately following the prompt for line 11.000 to indicate end-of-file, that is, that the last line of the file has been entered. (Control returns directly to TEL, rather than to Edit, because BUILD was given at the TEL level.)

```
11.000
```

**EDIT**

TEL prompts for another command. The user calls Edit again, explicitly this time, to use a command not available at TEL level.

```
EDIT HERE
*COPY PRIME ON PRIMES
```

Edit acknowledges its presence, and prompts. The user decides to change the name of his program file from PRIME to PRIMES, so he copies it to a new file named PRIMES.

```
*COPYING
*COPY DONE
*EDIT PRIMES
```

He then indicates that he wants to edit (actually only display) file PRIMES.

```
*TY 1-10
```

He indicates that he wants the whole file, lines 1 through 10, typed. (A larger ending number, e.g., TY 1-99, would do the same job.)

```
1.000 10 REM GENERATE PRIMES GR THAN 3
2.000 20 P=1
3.000 30 P=P+4, S=0
4.000 40 FOR I = 5 TO SQR(P) + 1 STEP 2
5.000 50 Q=INT(P/I)
6.000 60 IF Q*I=P THEN 80
7.000 70 PRINT P",TAB(0)
8.000 80 IF S=1 THEN 30
9.000 90 S=1, P=P+2
10.000 100 GOTO 40
*DELETE PRIME
```

Edit displays the copy, and prompts. The user sees that the copy is OK and decides to delete the original file, PRIME, so as not to tie up disk space unnecessarily.
The record editing mode is terminated for file PRIMES because file PRIME is to be processed. The above message is printed to indicate this.

He then indicates that he is finished with Edit.

and logs off.

- accounting summary -

MORE RECORD EDITING COMMANDS

Two more commonly used record-level commands are IN (Insert Records) and DE (Delete Records). The IN command is used to insert one or more lines between two records of a file or, alternatively, to replace one record of the file with the first (or only) insert line. (The IN command can be used to replace only one record, though more records may be inserted immediately following the replacement.) The IN command format is

\[ \text{IN } n[;i] \]

where

- \( n \) is the sequence number of the first or only line to be inserted.
- \( i \) is the optional increment value that Edit is to add to succeeding insertion-line sequence numbers.

Detailed rules for the use of IN are given following the next example.

The DE command deletes one or more (successive) records from the file. It has the format

\[ \text{DE } n[-m] \]

where

- \( n \) is the sequence number of the first or only record to be deleted.
- \( m \) is the optional end sequence number of a range of records to be deleted.

Example 13. Using EDIT to Modify a Source File

In this example, the user (after "desk-checking" his initial source program) sees that a logically required BASIC statement (NEXT) is missing, and inserts it. He then realizes that this original program will produce an endless listing of prime numbers, and prepares a different version, using MERGE to excerpt a portion of the original program for modification, and then to recombine this portion, after modification, with a copy of the original (thus, retaining the original version also).

The user suppresses further page headings by giving a page length of less than 12. (This practice is not recommended for normal production work, where the page headings delimit a uniform document size and provide useful identification: name, date, time, page number.)
He then indicates he wants to edit PRIMES.

He asks for display of lines 6 through end-of-program, i.e., line number 99 is in this case sufficiently large to include the whole file. (Note that "6-99" is equivalent to "6.0-99.0" or "6.000-99.000", etc.)

This message means: "End-of-file was found following line 10".

The user asks to insert a line numbered 6.5, to add the missing statement.

Edit prompts for the insertion-line with the line number. It then prompts for another command with an asterisk.

The user requests a display of lines 6 through 7, to see if the insert really worked.

He then asks for a portion of PRIMES to be copied on a new, empty file, NEWEND, and for the lines to be renumbered, starting with 7.

He requests a display to see if 7-11 was "excerpted" all right.

He requests an insert numbered 7.5, enters the insertion as shown below, and then requests an insert at the end of the file, i.e., line 12.
7.500 66 IF P > 1000 GOTO 110
7.500 66 IF P > 1000 GOTO 110
12.000 110 END
13.000 END

Edit prompts for another insertion, line 13; the user replies with an immediate @, signifying "done".

He then requests display of lines 7-12 (no line lower than 7 should exist).

7.000 65 NEXT I
7.500 66 IF P > 1000 GOTO 110
8.000 70 PRINT P'"TAB(0)
9.000 80 IF S=1 THEN 30
10.000 90 S=1, P=P+2
11.000 100 GOTO 40
12.000 110 END
*COPY PRIMES TO LOPRIM

He requests an extra copy of PRIMES on new file LOPRIM.

*EDIT STOPPED
*COPYING
*COPY DONE
*MERGE NEWEND, 7-12 INTO LOPRIM, 6.1-10

He then asks for a replacement of the original program lines 6.1-10, with the modified program ending from NEWEND.

*MERGE STARTED
--DONE AT 12.1
*EDIT LOPRIM
*TY 5-13

He requests display of lines 5 through end-of-file on LOPRIM.

5.000 50 Q=INT{P/I}
6.000 60 IF Q+P THEN 80
6.100 65 NEXT I
7.100 66 IF P > 1000 GOTO 110
8.100 70 PRINT P"TAB(0)
9.100 80 IF S=1 THEN 30

- accounting summary -

RULES FOR USE OF IN

The rules applicable to the IN command are summarized below. For ease of reference, the IN command format is repeated:

IN n[,i]

1. If n matches a sequence number already in the file, the first (or only) insertion line replaces the identically numbered line in the file.
2. If n does not match a sequence number in the file, the first (or only) insertion line n is inserted immediately following the next lower-numbered line (or at the beginning of the file if a lower line number does not exist).
3. If the insertion sequence number increment, i, is not specified, Edit assumes as a default value for i either the increment specified in the most recent record-level command given during the current Edit session, or the value 1 if no increment has been previously specified.
4. Following each record insertion, Edit prompts for further insertion lines with incremented sequence numbers, until either the incremented sequence number equals or exceeds a sequence number already existing in the file, or the user responds with a carriage return only. (In the first case, Edit rings the console bell and returns immediately to command-input mode, issuing an asterisk.)

RULES FOR USE OF MERGE

A more complete form of the MERGE command than initially presented is

MERGE fid1[n1[-n2]] INTO fid2,n3[-n4][i]

The optional increment value, i, was not previously presented. It is used to control renumbering of merged records. For example, by specifying a small fractional (decimal) increment it is possible to pack more records into the destination file than might otherwise be possible. The rules for MERGE are as follows:

1. The sequence numbers n3 - n4 specify the range of records to be deleted from the destination file (fid2), whether or not a one-for-one replacement occurs. (If n4 is omitted only record n3 is deleted, i.e., n3 is assumed as the value for n4.)

Edit 23
2. Sequence numbers \( n_1 - n_2 \) specify the maximum range of lines to be transmitted from the source file (\( \text{fid}_1 \)); default value of \( n_1 - n_2 \) is 1 through EOF. If \( n_2 \) is omitted, only record \( n_1 \) is merged. (The actual number of records moved is controlled by the next sequence value above \( n_4 \); see rule 4 below.)

3. Renumbering of the records from \( \text{fid}_1 \) in \( \text{fid}_2 \) proceeds from \( n_3 \), incrementing either by \( i \) or the default value, 1.

4. Records \( n_1 \) through \( n_2 \) are moved into the interval \( n_3 - n_4 \) on \( \text{fid}_2 \), renumbered, until either the incremented sequence number of a moved record equals or exceeds the sequence number of the successor of \( n_4 \), or the range of records \( n_1 - n_2 \) is exhausted.

5. Value \( n_2 \) may equal \( n_1 \); \( n_4 \) may equal \( n_3 \).

Note these characteristics of MERGE: (1) the number of \( \text{fid}_1 \) records moved is largely independent of the number of \( \text{fid}_2 \) records deleted; (2) sequence number discontinuities may be introduced into \( \text{fid}_2 \); and (3) by adjusting the increment value, the set of deleted records may be replaced by a much larger set of records. Note also that though it is a file-level command, MERGE has record-editing capabilities.

The rules for IN and MERGE can be used as a general guide to the operation of other record-level commands with similar formats.

**STRING SEARCH COMMANDS**

The string-search type of command involves an automatic search by Edit for the occurrence of a certain string of characters within specified columns of a range of records. The records are searched one at a time and, if a "hit" is made on one or more of the records, the action specified by the command is performed (type or delete record). You specify the range of records to be searched, the string to search for, and the record columns within which the search is to be made ("all" by default). Edit does the rest. Note that the line number is not considered a part of the record and that column 1 is the first character of the record.

Two string-search commands are available at the record-editing level.

- Find and Type Records.
- Find and Delete Records.

The command formats are

\[
\text{FT } n_1[-n_2]/\text{string}/[c_1\ldots c_2]\]

and

\[
\text{FD } n_1[-n_2]/\text{string}/[c_1\ldots c_2]
\]

where

- \( n_1 \) is the sequence number of the first or only record to be searched.
- \( n_2 \) is the sequence number of the last of a range of records to be searched (default value = \( n_1 \)).
- string delimited by slashes (/.../), is any sequence of characters that may exist in the file.
- \( c_1 \) is the number of the column at which the search is to start in each record (default value = 1).
- \( c_2 \) is the number of the column (inclusive) at which the search is to end in each record (default value = 140).

The specified string must be found entirely within the columns specified. The columns of a record (or line) are numbered from 1 through 140, and though 72 is the upper limit for a Teletype line, columns 73-140 may exist in a record, as discussed below. (Other string-search commands are available at the intrarecord-editing level, and are generally more useful and efficient than those described above.)
HOW TO ENTER MULTILINE RECORDS

On a terminal unit having an inherent line-width limit of less than 140 (e.g., Teletype models 33, 35, and 37), a single, multiline record may be entered into a file (using the BUILD or IN commands, for example) in either of two ways:

1. Using the local-carriage-return key marked LOC CR, if present, to "break" the input line without releasing it to the system.

2. Using the simulated local-carriage-return sequence $\theta$ for the same purpose.

Either method permits entering a record of up to 139 characters plus $\theta$ on virtually any terminal unit.

Example 14. Using String-Search Commands and Local-Carriage-Return

```
: 
!EDIT $\theta$
EDIT HERE
*COPY LOPRIM TO SCRATCH $\theta$

The user copies his program to a new file in order to experiment with FT, FD, and IN.

*EDIT SCRATCH $\theta$
*FT 2-15,/$\theta$/ $\theta$

He requests a search of records 2 through 15, all columns, for the character string "$P="", with the record displayed on each hit.

2,000 20 P=1
3,000 30 P=P+4, S=0
10.100 90 S=1, P=P+2
--EOF HIT AFTER 12.1
*FT 1-13,/$\theta$/ $\theta$

He then asks for a search on "$=P" in lines 1 through 13.

3,000 30 P=P+4, S=0
6,000 60 IF Q$\theta$I=P THEN 80
10.100 90 S=1, P=P+2
--EOF HIT AFTER 12.1
*FT 1-2,/$\theta$/ $\theta$

He now asks for a search on "PR" in lines 1 through 2.

1,000 REM GENERATE PRIMES OVER 3 AND UNDER 1000
1.100 REM (THIS PROGRAM IS A LIMITED VERSION OF
1.200 REM MY PROGRAM "PRIMES", WHICH HAS NO
*FT 1-2, REM/,4,60 $\theta$

He tries a "negative" test of the column-delimiting capabilities,

--NONE
*FD 1.1-2, REM/ $\theta$

then a find-and-delete of records 1.1 through 2, inclusive, containing "REM".

--003 RECS DLTED
*TY 1-6 $\theta$

He requests display of results.
```
1.000 REM GENERATE PRIMES OVER 3 AND UNDER 1000
2.000 20 P=1
3.000 30 P=P+4, S=0
4.000 40 FOR I=5 TO SQR(P)+1 STEP 2.
* IN 1.5 @
1.500 REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)

He tries to reenter former lines 1.1 and 1.2 as one record, with a local line-break (@).

*PR 1-3, /REM/@
1.000 REM GENERATE PRIMES OVER 3 AND UNDER 1000
1.500 REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)

Note, (1) that the user neglected to supply a blank (or space) following "of" prior to or after the local carriage-return, and (2) that the system "folds" the record indiscriminately when the physical line-width limit is reached.

*END @

INTRADECORD COMMAND USAGE

The intrarecord commands make changes within an individual record. They generally manipulate character strings. Intrarecord commands may only be given after the user selects an intrarecord mode with the SE, SS, or ST command. The SE command will be discussed below as an example of selecting an intrarecord mode.

The SE (Select Intrarecord Mode) command simply selects a range of records, and optionally a field within each record, for subsequent intrarecord "processing" commands to operate on. The selection remains in effect for any number of subsequent commands until a new selection is made or a record editing command is given.

After the SE is given, Edit prompts for further commands. You can then issue one processing command or several commands separated by semicolons (;) on the same input line.

If one command is issued per line, the processing specified by that command is performed against each record in the range specified by the SE. However, if more than one command is issued per line the whole set of commands will be processed successively against the first record, then against the second record, etc. (Obviously, if the range selected is only one record, the result is the same in either case.)

The format of the SE command is

\[ SE n_1[-n_2][c_1[c_2]] \]

where the meanings and defaults of the record and column selection parameters are the same as for the FT and FD string-searching commands.

Two very useful and similar processing commands are S (String Substitution) and D (Delete String). The S command format is

\[ *[j]/string_1/S/string_2/ \]

where

string_1 is the string to be searched for.
string_2 is the string to be substituted in place of string_1.
is an integer that indicates that only the jth occurrence of string 1 within the search field of each record is to be replaced by string 2 (default value = 1). If all occurrences of string 1 are to be replaced, j must be specified as zero.

The D command format is

\[ [j]/\text{string}/D \]

where

- string is the string to be deleted.
- j has the same meaning as in the S command.

Note that when substituting a longer string for a shorter string, the remainder of the line (if any) is moved right only as far as needed to preserve a single-blank separator if at least one blank existed to the right of the original string. That is, in certain cases multiple blanks to the right of the insert may be lost. (This is useful in preserving columnar alignment.)

In this regard, you may include initial, embedded, or terminal blanks (i.e., spaces) in either string. Edit treats the blank in general like any other printing character, the major exception being the suppression of multiple blanks in certain cases of string substitution and deletion. (A Blank-Preservation-Mode command, BP, in intrarecord operations provides for cases where multiple blanks must not be lost, as in "quoted" character-string literals.)

A number of other very useful, more specialized intrarecord commands exist for record modifications, but most of these are logical shortcuts to results that can usually be achieved with S and D commands only.

The two intrarecord display commands, TY (Type, Including Sequence Number) and TS (Type, Suppressing Sequence Number) are analogous to their record-level counterparts, but do not specify record numbers (i.e., you enter TY or TS only). With or without sequence numbers, the commands display the currently active record(s), as illustrated by the following example.

Example 15. Using Intrarecord Commands

```
EDIT SCRATCH @
EDIT HERE
*FT 1-2,/PROG/@

The user enters the FT command to find and type lines containing PROG, within the range 1 through 2, inclusive. (Only line 1.5 should satisfy the requirement.)

1.500 REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)
*SE 1.5 @

He then enters the intrarecord mode selection command, which is required to fix the error in the line by string substitution.

*/OPRO/S/OFP PRO/@

He substitutes OF PRO for OFPRO (first instance only: j = 1 by default).

*TY @
1.500 REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)
*TS @

To see if the line-break problem in line 1.5 would disappear if the line were displayed without its sequence number (as will happen under the BASIC subsystem), he uses the TS command.
```
REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)
*0/P/S/N/ ©

This does in fact solve the problem. Now he wants to change all program variables named P to Ns. (This will have no effect on the program, since we have no variables named N.)

*TY ©
1.500 REM (THIS PROGRAM IS A LIMITED VERSION OF PROGRAM "PRIMES", WHICH HAS NO SET UPPER LIMIT.)

He forgot to reset the range selection (SE).

*0/N/S/P/ ©
*SE 2=13 ©
*0/P/S/N/ ©

He reverses the N for P substitution in line 1.5, then sets proper range, and tries his original substitution again;

9 STRINGS CHANGED
--EOF HIT AFTER 12.1
*TY ©

and checks the result.

2.000 20 N=1
3.000 30 N=N+4, S=0
4.000 40 FOR I=5 TO SQR(N)+1 STEN 2
5.000 50 Q=INT(N/I)
6.000 60 IF Q*I=N THEN 80
6.100 65 NEXT I
7.100 66 IF N>1000 GOTO 110
8.100 70 NRINT N"TAB(0)
9.100 80 IF S=1 THEN 30
10.100 90 S=1, N=N+2
11.100 100 GOTO 40
12.100 110 END
--EOF HIT AFTER 12.1

The substitution worked, except that it was not possible to delimit the search string narrowly enough; STEP to STEN, and PRINT to NRINT, were changed as well.

*/STEN/S/STEP; /NR1/S/PRI ©

This reverses the change.

*SE 4;TY ©

The user requests a display of line 4 and, below, of line 8.1.
Since he did not actually need this file, he deletes it.

```
:EDIT STOPPED
:DELETED
:END
:OFF
```

- accounting summary -

**TEL EDITING COMMANDS VS EDIT COMMANDS**

The TEL command !EDIT fid implies the sequence

```
!EDIT
*EDIT fid
```

The TEL command !BUILD implies the sequence

```
!EDIT
*BUILD
```

Both are, therefore, shortcuts provided for your convenience. However, note that the TEL EDIT command must be given before the Edit COPY command can be used, as distinct from the TEL COPY command. The TEL COPY command implies a call to the PCL subsystem; the COPY command under PCL is different from the Edit COPY command in scope, intent, and format.

TEL/PCL COPY and other PCL commands are described in the next section.

**PCL**

The Peripheral Conversion Language, PCL, provides you with on-line facilities for initiating and controlling:

- Movement of files between peripheral storage devices.
- Movement of files between peripheral storage devices and RAD or disk pack storage (or other forms of secondary storage).
- Movement of files within disk storage.
- Concatenation of files and selection of records from files during file movement.
- Data-record formatting and code conversion during file movement.
- Deletion of files.
- File building on any type of device or storage media from an on-line terminal.
• Display of peripheral input-device files or RAD or disk pack files on an on-line terminal.
• Listing of a RAD or disk pack file directory or of file names on a labeled magnetic tape.
• Positioning (and releasing) of magnetic-tape volumes.

The peripheral storage devices referred to may be

1. Magnetic-tape drives: Xerox labeled, ANS labeled, or unlabeled tape.
2. Unit-record devices: card punch and line printer (card reader cannot be requested on-line).

As mentioned before, one common characteristic of peripheral devices is that they generally require operator intervention, e.g., for the mounting and dismounting of physical file volumes. Therefore, an on-line user must be specially authorized in order to be able to use these devices via PCL (or any other on-line means); otherwise he will simply receive an error message on any attempt to do so.

Many of the facilities listed above are mainly of interest to the experienced on-line user doing the kinds of programming that were heretofore necessarily restricted to central-site batch operations: commercial and large-scale scientific applications involving large volumes of input and output data, system development, etc. Actually, the complete set of PCL facilities, plus the TEL SET command and direct user-to-operator messages, provide control of total system resources analogous to that obtainable only with “hands on”, central-site batch operations under previous systems.

We will describe only the PCL functions commonly used by all on-line users. These include keyed-file merging, building of unkeyed files, concatenation of unkeyed files, terminal display of either type of file, listing of file names, and file deletion.

**PCL COMMANDS**

The PCL COPY, L (which is the TEL form of the PCL LIST command), and DELETE commands may be given at TEL level, but PCL must be called explicitly (!PCL) for all other PCL commands. PCL prompts for command input with the less-than (<) character, and for file input and responses to questions with a period.

The PCL commands covered here are COPY, LIST, DELETE, and DELETEALL. COPY allows a vast array of options in its variable field; it is the workhorse of the PCL language. Therefore, only a subset of the possible variations of the command is described here.

The COPY command format is

```
 COPY sd[/fid[/fid]. . . TO OVER dd[/fid]
```

where

- **sd** may be DC, CR, ME, operational label, stream-id, or:
  - DP#serial no.[-rt]
  - LT#serial no[-rt]
  - AT[#serial no.][-rt]
  - FT#serial no.[-rt]

  where **rt** is the 2-character identifier of a device that was defined at SYSGEN to be a resource.

- **fid** is a file identification, for DC, DP, LT, or AT files only; normally only a file name.

*Wherever TO is specified, ON may be substituted.*
dd may be DC, CP, LP, ME, operational label, stream-id, or:

DP[serial no.][-rt]
LT[serial no.][-rt]
AT[serial no.][-rt]
FT[serial no.][-rt]

where rt is the 2-character identifier of a device that was defined at SYSGEN to be a resource.

Each PCL identification can be followed immediately by one or more special options in parentheses; i.e., d (option) or d/fid (option). If the default device code DC is not explicitly specified, the slash (/) preceding fid may be omitted; see the following example.

If TO is specified, a new file is created (and must not already exist). If OVER is specified, the output file may exist and if it does it will be deleted and replaced by a copy of the input file. The TO/OVER clause is optional following a prior COPY specifying a TO/OVER destination file or device (during the same session with PCL). If the TO/OVER clause is omitted under these circumstances, the last-named file will be extended according to the file-convention. A subsequent TO/OVER clause or an exit from PCL terminates file extension.

If multiple source files — e.g., FILA, FILB, FILC — are specified, the several file contents are either concatenated, i.e., joined end to end, on the destination file in the case of unkeyed files, or merged on the basis of record-key values in the case of keyed files. Both cases are illustrated in the following examples.

The remaining commands to be discussed in this introduction to PCL are LIST, DELETE, and DELETEALL.

LIST lists all your disk-file names (i.e., all names in your account directory). This is the simplified form of the LIST command. Additional specifications allow the user to list the files that are on a particular device.

DELETE replaces the specified files. The rt option specifies the 2-character identifier of a device that was defined at SYSGEN to be a resource.

DELETEALL deletes all files in the log-on account if 'from' and/or 'to' are not specified. Deletes a range of files in the log-on account if 'from' and/or 'to' are specified. 'From' and 'to' are sort keys or file names. The rt option specifies the 2-character identifier of a device that was defined at SYSGEN to be a resource. With this command, PCL asks for a confirmation:

DELETEALL?

"YES$" is the only correct positive response.

Example 16. Keyed-File Update and Display, Using PCL COPY

The user wants to produce another version of the PRIMES program that will allow him to set, via the terminal, the range of the prime numbers produced during each run. He creates the modification files using Edit BUILD, but uses PCL COPY to achieve the actual file updating.

BUILD MOD1,1,.125

The user wants to build a file starting with sequence number 1 and incrementing by only .125, instead of the standard (default) increment of 1. Note that we have added an i parameter (.125) to BUILD that corresponds to that of MERGE and INSERT.
REM GENERATE PRIME NUMBERS (>3) WITHIN USER-SET LIMITS

PRINT 'ENTER LOWER BOUND FOR PRIMES'
INPUT L
PRINT 'ENTER UPPER BOUND FOR PRIMES'
INPUT U
BUILD MOD2,7.1,.5

He requests a second new file, starting with sequence number 7.1, but incrementing by .5 in this case.

IF P<L THEN
IF P<U THEN
COPY LOPRIM,MOD1,MOD2 TO VPRIM

He requests PCL to copy files LOPRIM, MOD1, and MOD2, in succession to form new file VPRIM. Note that these are keyed files, and as such are not simply linked together end-to-end on VPRIM. MOD1 is merged with LOPRIM, records from MOD1 replacing any records from LOPRIM having matching keys, and all nonmatching records falling into their natural sequence. The same process is repeated between MOD2 and the results of LOPRIM,MOD1 — and so on if more files were specified. (The source files themselves are not modified in any way.) However, the three input files may be concatenated without loss of any records by using the LN option (after VPRIM in the command) to assign new keys.
He displays the results directly, using the PCL COPY command. Note that ME is a PCL identification code, not a name; VPRIM, not being a PCL identification code, is understood by default as DC/VPRIM.

He displays the results directly, using the PCL COPY command. Note that ME is a PCL identification code, not a name; VPRIM, not being a PCL identification code, is understood by default as DC/VPRIM.

The user then displays the same results using Edit.

The last example points to several differences between the Edit COPY and the PCL COPY: The Edit COPY can only specify disk filenames; the PCL COPY can specify or imply devices (e.g., ME, DC, LT) and filenames, either singly or in combination as appropriate. Note that the specification DC/ME is possible and results in no ambiguity, though in this case "DC/" must be specified or the file name may be written as 'ME'. A second difference is that the PCL COPY TO ME, though it accepts keyed files, does not display the keys as sequence numbers as does Edit TY; it is functionally the same as Edit TS in this respect.

The output option K must be used to display keys (in addition to the record sequence numbers) in a format comparable to the Edit TY display.
The next example is designed simply to illustrate these differences as well as to further clarify the merging action of PCL COPY on keyed files.

Example 17. Keyed-File Update and Display (Further Examples)

```plaintext
; BUILD FILA
1,000 LINE 1 IN FILA
2,000 LINE 2 IN FILA
3,000 LINE 3 IN FILA
4,000 LINE 4 IN FILA
5,000

BUILD FILB,.5,.5

Here the user requests a new file starting with sequence number .5 and incrementing by .5 also

0.500 LINE 1 IN B
1.000 LINE 2 IN B
1.500 LINE 3 IN B
2.000 LINE 4 IN B
2.500 LINE 5 IN B
3.000 LINE 6 IN B
3.500 LINE 7 IN B
4.000

BUILD FILC,2,.75

and a new file starting at 2 and incrementing by .75.

2.000 LINE 1 IN C
2.750 LINE 2 IN C
3.500 LINE 3 IN C
4.250 LINE 4 IN C
5.000 LINE 5 IN C
5.750 LINE 6 IN C
6.500

COPY FILA,FILB,FILC TO DC/ME

He combines the three files on new disk file ME.

COPY DC/ME

With PCL COPY he displays file ME on device ME.

LINE 1 IN B
LINE 2 IN B
LINE 3 IN B
LINE 1 IN C
LINE 5 IN B
LINE 2 IN C
LINE 6 IN B
LINE 3 IN C
LINE 4 IN FILA
LINE 4 IN C
LINE 5 IN C
LINE 6 IN C

EDIT ME
EDIT HERE
TY .5-6

Then he displays it with Edit.
```
Note that the merging action of the multiple-file PCL COPY eliminates duplicately keyed records on file ME by successive replacement: record n from FILB replaces record n from FILA, and is in turn replaced by record n (if any) from FILC. Only record 4.000 survives from FILA, for example. If the LN option had been used on output, all records in the three input files would have been kept, and the records in file ME would be assigned new keys.

Example 18. Building and Concatenating Unkeyed Files

In this example, the user creates two unkeyed files using PCL COPY; in most real instances of file concatenation, however, the files are outputs of other processors, e.g., FORTRAN. The user copies the files in the desired order to a single new file. A display of the resultant file shows the ordering of records produced by a multiple unkeyed-file copy. This example also shows how to copy a file to the system line printer. (Note that permission for such use of central-site peripherals requires explicit installation authorization; the system carries a record of this authorization.)

The user requests a copy of terminal input to file A.
He enters input to new file A from the terminal. PCL prompts for input of each data line. An Escape F sequence ends the data input, i.e., indicates end-of-file.

He enters input to new file B from the terminal.

He copies files A and B in succession to form new file C, incidentally showing the syntax of explicit device identification (optional) in the case of multiple-file specification.

He now copies the contents of file C to the terminal.

He then asks PCL to print file A on the system printer.
5. USING LANGUAGE PROCESSORS

INTRODUCTION

The term "language processor" refers to a processor that processes a specific programming language. Such processing consists essentially of some form of translation of the source language to the internal language of the computer, or machine language. (This machine-language translation is also commonly referred to as "object code").

The most frequently used language processors available under CP-V in on-line mode are BASIC, Extended FORTRAN IV, ANS COBOL, Meta-Symbol, and APL. Although these processors are also available for batch mode operations, this guide is limited to a description of their on-line usage.

It is important at this point to distinguish between a programming language and the on-line command language associated with it. You use statements (i.e., sentences) of the programming language to form a program, whereas the commands are used to control what is done to or with that program. This chapter is intended to illustrate elementary uses of the command languages. (Succeeding chapters cover increasingly complex usages.) Therefore, to understand the program content of any of the following examples, knowledge of the relevant programming languages is necessary.

The following manuals contain descriptions of the language processors:

BASIC

The CP-V BASIC processor is a compiler for a significantly extended and enhanced Xerox version of the standard BASIC language (Beginner's All-Purpose Symbolic Instruction Code), a mathematical language designed specifically for time-sharing usage.

BASIC is particularly suited to small and medium scale computational applications. The outstanding advantage of BASIC is that it is easy to learn and simple to use. It is an ideal "starter" language, even though it does offer sophisticated problem-solving capabilities.

The BASIC processor is called with the TEL command BASIC. The processor then prompts for either BASIC program statements or BASIC commands with a "greater than" (>) character. During program execution, it prompts for program-requested terminal input (if any) with a question mark (?). When you have finished using BASIC, you exit back to TEL by giving the SYSTEM command.

Since BASIC includes a program-building and editing facility, a program file need not be built under EDIT (as is the general case for FORTRAN and Meta-Symbol programs).

A useful Xerox enhancement of BASIC is its capability for direct execution of individual statements. This allows you to operate BASIC in the "desk-calculator mode", without building a program; it also provides a powerful on-line debugging feature. These topics are discussed in a later section of this chapter.

PROGRAM BUILDING, EDITING, AND EXECUTION

Having called BASIC, you build a source program simply by entering BASIC program statements — each beginning with the required one to five digit step number (see following example) — in response to the prompt character (>). Typing error corrections can be made before the line is released with the @, @X, or X controls as usual. Program statements entered in this fashion reside in an internal program-text area and constitute the current program.
The complete set of statements that are to constitute a given program need not be entered consecutively (e.g., BASIC commands may intervene) and need not be entered in a sequence corresponding to their step numbers. The step numbers of the individual statements completely control the logical ordering of the statements within the program, providing for automatic insertion, replacement, and deletion of single statements on the basis of relative step numbers, as follows:

- **Insertion** - A statement entered with a step number falling in numerical sequence between the step numbers of two previously entered statements is automatically inserted between those two statements.

- **Replacement** - A statement entered with a step number matching the step number of a previously entered statement automatically replaces that previously entered statement.

- **Deletion** - A step number followed immediately by \( \|$ \), i.e., a "null statement", causes any previously entered statement having a matching step number to be deleted.

(Explicit editing commands that can affect more than one statement are covered in a subsequent section.)

After entering a program in this manner, you can have it compiled, error-checked, and executed (if no detectable errors exist) by issuing the RUN command. Syntax (i.e., language) errors, if any, will be reported by BASIC, and a prompt character (\( » \)) issued. You may at this point correct these errors, via statement insertion, replacement, or deletion as described above. Note that when terminal input is requested by your program during its execution, a question mark (\( ? \)) is issued as a prompt character.

Once a program has been tested and is known to be working correctly, you can request subsequent execution with the command FAST instead of RUN. FAST bypasses the checking of indices for subscripted variables.

The following example illustrates three intrinsic -or built-in- functions: "DEG(x)" - convert x from radians to degrees; "ASN(x)" - calculate arcsin of x, in radians; and "ABS(x)" - use absolute value of x. The first two, "DEG and "ASN, are specific CP-V additions to the standard BASIC language.

**Example 19. BASIC Program Building, Editing, and Execution**

```
10 REM SAMPLE PROGRAM
20 $A = "COMPUTE ARCSINE OF X, IN DEGREES"
30 PRINT $A
40 FOR I = 1 TO 5
50 INPUT X
60 PRINT DEG (ASN(X)) " = ARCSIN OF "X
70 NEXT I
80 END
```

He enters the final statement (step 80) and then requests compilation and execution with the RUN command.
16:18  NOV 09 RUNIDAA...
COMPUTE ARCSINE OF X, IN DEGREES
1.001
5.72958E-02 = ARCSIN OF 1.00000E-03
2.707
44.9913 = ARCSIN OF .707000
2.070
-44.9913 = ARCSIN OF -.707000
2.076

He now tries a value that is much too large.

60 ASN-ACS ARG ERROR

He gets an error message, and a return to editing/command level (where he will enter additional program statements for detecting the out-of-range condition).

55 IF ABS(X) > 1 THEN 90
90 PRINT X; "VALUE OUT OF RANGE"
95 GOTO 70
RUN

After inserting steps 55, 90, and 95, he tests again.

16:27  NOV 09 RUNIDAA...
COMPUTE ARCSINE OF X, IN DEGREES
1.50000 VALUE OUT OF RANGE
?

He gets the desired result on the exception condition, and terminates execution.

PROGRAM SAVING, LOADING, AND RENAMING

A program created under BASIC can be saved on a permanent file with the SAVE command, and can be subsequently reloaded for execution with the LOAD command. The command form SAVE ON filename (where filename does not name an already-existing file) creates a file named as specified, on which your current program is copied. If, on the other hand, you use the command SAVE OVER filename, your current program is copied on the named file. If the specified name is not that of an already existing file, a new permanent file is created.

To retrieve a saved program, you use the command LOAD filename. In general, the LOAD command causes loading of the named program into the program-text area, but the results of this loading will depend upon the state of this area at the time the command is given. If the program-text area is empty, i.e., no current program has been entered or loaded during the current BASIC session, the saved program simply becomes the current program.

If, however, the program-text area is not empty at the time of the LOAD, the result depends on the current operating mode, or status. If the status is not "running", i.e., not execution mode, then the statements of the saved program are "woven" into the current program, on the basis of step numbers. This "weaving" process is analogous to a linked-file PCL COPY f_1,f_2 to f_3.

The result is not usually the one desired; it can be circumvented by using the command CLEAR, prior to the LOAD. The CLEAR command clears the contents of the program-text area, i.e., the current program. This command may be given at any time. If BASIC is in execution mode, or "running", the program-text area is automatically clear prior to loading. The operating mode can be ascertained at any time by use of the
STATUS command. Use it frequently to become familiar with mode transitions. (The responses to STATUS are EDITING, COMPILING, or RUNNING.)

ADDITIONAL EDITING FACILITIES

Two BASIC editing commands that facilitate the display and deletion of current-program statements are LIST and DELETE, respectively. These two commands have identical formats; LIST is shown:

LIST \([s_1 \rightarrow s_2]\)[,\(s_3 \rightarrow s_4\)]...

where \(s_i\) is a step number.

If one or more pairs of dash-separated step numbers \((s_1 \rightarrow s_2, \text{etc.})\) are specified, the corresponding range(s) of statements are listed or deleted. If only \(s_1\) \((s_2, \text{etc.})\) is specified, only the corresponding individual statement(s) is listed or deleted. If no step number is specified in a LIST command, the entire current program is listed.

Note: The command form DELETE \(\text{@)}\) is ignored; to delete the entire program you must use the CLEAR command.

Example 20. Program Modification, Saving, and Reloading

(This example takes up at the point at which we left Example 19.)

\(\geq 10 \text{@)}\)
\(\geq 15 \text{@)}\)

The user deletes the two REM statements (which are not necessary to the program's operation) and, below, requests a display (LIST) of the current program.

\(\geq \text{LIST @)}\)
\(20 \text{ $A = "COMPUTE ARCSIN OF X, IN DEGREES" } \text{@)}\)
\(30 \text{ PRINT $A}\)
\(40 \text{ FOR } I = 1 \text{ TO 5}\)
\(50 \text{ INPUT X}\)
\(55 \text{ IF } \text{ABS}(X) > 1 \text{ THEN 90}\)
\(60 \text{ PRINT DEG (ASN(X)) } = \text{ ARCSIN OF } "X"
\(70 \text{ NEXT } I\)
\(80 \text{ END}\)
\(90 \text{ PRINT X: "VALUE OUT OF RANGE" @)}\)
\(95 \text{ GOTO 70}\)
\(\geq25 \text{ REM NEXT STMT SHOWS STRING CONCATENATION (+) @)}\)
\(\geq30 \text{ PRINT $A + ", TESTING FOR OUT-OF-RANGE VALUES" @)}\)
\(\geq40 \text{ FOR } I = 1 \text{ TO 2 @)}\)
\(\geq \text{LIST 20-40 @)}\)

He inserts step 25, replaces steps 30 and 40, and lists steps 20 through 40 to observe the results.

\(20 \text{ $A = "COMPUTE ARCSIN OF X, IN DEGREES" } @)}\)
\(25 \text{ REM NEXT STMT SHOWS STRING CONCATENATION (+) @)}\)
\(30 \text{ PRINT $A + ", TESTING FOR OUT-OF-RANGE VALUES" } @)}\)
\(40 \text{ FOR } I = 1 \text{ TO 2 @)}\)
\(\geq \text{RUN @)}\)
\(14:53 \text{ NOV 10 RUNIDAA...}\)
\(\text{COMPUTE ARCSIN OF X, IN DEGREES, TESTING FOR OUT-OF-RANGE VALUES}\)
\(? .253877 @)}\)
\(14.7071 = \text{ARCSIN OF .253877}\)
\(? =.00000009 @)}\)
\(-5.15662E-06 = \text{ARCSIN OF -9.00000E-08}\)

80 \text{HALT}
PRINT "ENTER SINE VALUE, PLEASE"

He inserts a final modification, then saves the program on new permanent file ARCSINE.

SAVE OVER ARCSINE
CLEAR
LOAD ARCSINE

After clearing the program-text area, he loads the saved copy back in, and tries it once more (note the new current-program name when he executes it again).

RUN

15:04 NOV 10 ARCSINE...

COMPUTE ARCSIN OF X, IN DEGREES, TESTING FOR OUT-OF-RANGE VALUES
ENTER SINE VALUE, PLEASE
? .001
5.72958E-02 = ARCSIN OF 1.00000E-03
ENTER SINE VALUE, PLEASE
? .002
.114592 = ARCSIN OF 2.00000E-03

80 HALT

TEMPORARY SAVING, RENAMING, AND RENUMBERING OF CURRENT PROGRAM

The FILE and NAME commands, used in conjunction with CLEAR and LOAD, provide a convenient short-cut means of temporarily saving the current program, e.g., for "backup" purposes prior to extensive modification, and of renaming the current program for the execution-report heading. (You will have noticed a default program name, i.e., RUNIDAA, in the previous examples — this default name varies from session to session.)

The command FILE simply causes the current program to be copied onto a temporary file (known as the "runfile" in other Xerox operating-system environments). This copy of the program can be explicitly named by using the command NAME newname prior to the FILE command. If the NAME command is not used (or no name is specified) the default program name applies. At any point after a program has been FILEd, a CLEAR and then a LOAD, with no filename, reestablishes the field copy as the current program. The copy will remain on file during the whole terminal session until another program is FILEd over it.

When using FILE and LOAD (no name), it is important to remember that these commands always refer to the last runfile referred to with a NAME command, if one or more have been issued. If not, the default runfile name is "current". (The default runfile name can be reestablished with a null NAME command, i.e., simply NAME.

Multiple runfiles can exist concurrently, resulting from multiple pairs of NAME newname and FILE commands having been issued; they can be selectively retrieved by a LOAD name command. Note: If NAME newname is used, newname may not also be used as the name of a permanent file during the same terminal session.

The command sequence for changing the execution name of a current program would be

NAME newname
FILE
CLEAR
LOAD
Note that in this instance the CLEAR command that precedes the LOAD is functionally unnecessary since the current program and the filed program are identical, but it is included because of resultant savings in processing time and space.

At any time you can cause your current program to be automatically renumbered by giving a RENUMBER (or REN) command. Its format is

\[ \text{RENUMBER} \{s_1 \} \{s_2 \} \{i\} \]

where

- \( s_1 \) is the initial new step number (default value = 100).
- \( s_2 \) is the old step number at which to begin renumbering (default value = 1, i.e., "first statement").
- \( i \) is the increment by which successive new step numbers are to be increased (default value = 10).

(For example, REN alone is equivalent to RENUMBER 100, 1, 10; REN, 10 equivalent to RENUMBER 100, 10, 10; REN,, 5 to RENUMBER 100, 1, 5.)

This command allows you to clean up, or regularize, the numbering of your program with full control over the starting value, the point in the program at which to begin, and the step-value spacing. During the renumbering process, proper replacements are made for all step-number references, i.e., in GOTO statements, THEN clauses, etc., within the program. If the renumbered program was loaded from a permanent file, simply resaving it over the same file will make the renumbering "permanent".

Example 21. Temporary Filing, Reloading, and Renaming

```
: :  
(Continued from previous example.)

>FILE "2"

The user files the current program (ARCSINE) on a temporary "runfile", under the default "runfile" name - whatever that is.

>CLEAR "2"

He then clears the current program, to play safe.

>LOAD VPRIM "2"

>RUN "2"

He loads and executes the program VPRIM, previously built under Edit. (If it were now to be resaved over VPRIM, that file would no longer be keyed, as BASIC is not a keyed-file oriented processor - BASIC step numbers are part of the file records, not record keys.)
```
Following a successful execution of VPRIM, he requests the current status of BASIC.

RUNNING

He now loads the default-named temporary file, without a preceding CLEAR, since clearing is automatic in execution mode.

>LOAD

He breaks off execution, names another temporary "runfile", and (below) files the current program on it.

>FILE
>CLEAR
>LOAD

Note here that LOAD with no name specified will refer to the last-named "runfile" (if any—otherwise to the default-named "runfile").

>RUN

This command, SYS, causes an exit from BASIC and a return to TEL.

DIRECT STATEMENT EXECUTION AND DESK-CALCULATOR MODE

Direct statements are BASIC statements entered without a step number either in editing or execution mode. They can be executed either with or without a current program—the latter being called "desk-calculator mode". In normal execution mode, i.e., with a current program, direct statements are used for on-line debugging, or program verification.
Direct statements are recognized as such by BASIC and are executed (if possible) immediately. The most commonly used forms of direct statements in editing or desk-calculator mode are PRINT statements containing an arithmetic expression, and one or more LET statements followed by a PRINT statement. For on-line debugging, GOTO, LET, and PRINT are commonly used, singly or in combination, referring to variables and statements in the current program.

Most BASIC statements can be issued as direct statements; the few exceptions, e.g., FOR, NEXT, are statements that cannot be expected to "execute" by themselves in any meaningful way.

A further enhancement of the direct-statement execution capability is the EXECUTE (or EXE) command, which is provided specifically for convenience in on-line debugging and verification. The command format is

```
EXECUTE[s1][s2]
```

where \( s_1 \) and \( s_2 \) refer to step numbers in the current program.

In either editing or execution mode, a step number reference causes one statement or a range of statements of the current program to be executed. Note that if a range is specified, the last statement in the range, \( s_2' \), is not executed. (You can achieve the same effect by combinations of direct statements, but the EXECUTE command is significantly faster and more convenient.)

Example 22. Use of Direct Statements – "Desk-Calculator Mode"

```plaintext

## Desk-Calculator Mode

```

The user calls BASIC and immediately enters a direct statement, i.e., one with no line number. Note that (1) there is no current program, and (2) the user doesn't have to be in execution mode.

```

10,0000

30,0000

>PRINT DEG(ASN(1.1))

Now he tries one that should result in an error comment.

```

ASN-ACS ARG ERROR

>LET X=SQR(2)/2

Then he tries a sequence of two statements with a common variable.

```

>PRINT DEG(ASN(X))

65,0000

>OFF

--accounting summary--

```
ABBREVIATIONS OF BASIC COMMAND VERBS

All of the BASIC command verbs may be shortened to the first three letters, i.e., CLE(ar), DEL(ete), LOA(d), etc. In addition, you may use the following short forms of the SAVE command: SAV N for SAVE ON, and SAV VER for SAVE OVER.

Another direct-statement execution example follows, illustrating EXECUTE command usage.

Example 23. Using the EXECUTE Command

```
1 BASIC
2 >LOAD VPRIM
3 >1 PRINT 'P='P;'I='I;'Q='Q;'S='S

   The user inserts a statement that facilitates inspection of variable values as he executes selected portions of it below.

>LIST
1 PRINT 'P='P;'I='I;'Q='Q;'S='S
10 REM GENERATE PRIME NUMBERS (>3) WITHIN USER-SET LIMITS
20 PRINT 'ENTER LOWER BOUND FOR PRIMES'
30 INPUT L
40 P=1
50 P=P+4,S=0
60 FOR I=5 TO SQR(P)+1 STEP 2
70 Q=INT (PI/P)
80 IF Q*I=P THEN 150
90 NEXT I
100 IF P<L THEN 150
110 IF P>U THEN 180
120 PRINT P,TAB (0)
130 S=S+1, P=P+2
140 GOTO 80
150 U=50
160 GOTO 10
170 END
>RUN
13:02 NOV 18 VPRIM ...
P=0 I=0 Q=0 S=0

ENTER LOWER BOUND FOR PRIMES
?17
ENTER UPPER BOUND FOR PRIMES
?17
17
180 HALT
>EXE 1
P= 19 I= 5 Q= 3 S= 1
>EXE 70-120

120 -EXEC- HALT
>EXE 1
P= 23 I= 5 Q= 4 S= 0
>LET U=50

Here the user enters a direct statement to change the upper-bound parameter.

>EXE 110-150
23
150 -EXEC- HALT
```
The Extended FORTRAN IV processor is a mathematical-language compiler that processes an extended version of the standard FORTRAN IV language. It is appropriate to the solution of medium-to-large scale computational problems, and offers full file input/output capabilities. Unlike BASIC—compile-and-execute processor—it produces savable and reusable object programs, eliminating the need to recompile frequently used programs.

A related facility, the FORTRAN Debug Package (FDP), permits on-line debugging during program development and checkout. Use of FDP is covered in Chapter 7, "Debugging User Programs." FORT4 accepts source-program input either from a previously built source file or directly from the user's terminal, line at a time. Normally, the former method is employed, the file having been built with the Edit processor.

The line-at-a-time method has an advantage for novice FORTRAN users in that "conversational" syntax-error diagnostic comments are issued immediately following input of the line to which they refer, an effective learning device. (When using this method, a source file can be preserved for subsequent modification and recompilation by means of the special compilation option SO, and an appropriate ISET command, as shown in a subsequent example.)

The standard outputs of the compilation process are the compiled object program, called the relocatable object module (ROM), and error comments. A listing of the source program may be (and generally is) requested, with the LS compilation option, described below.

CONTROLLING THE COMPILATION PROCESS

FORT4 is called with the TEL command FORT4. The format of this command is:

```plaintext
FORT4 [source] [ON] [OVER] [rom] [,list]
```

where

- `source` specifies a disk file containing the source program.
- ME indicates source input from the user's terminal (the default assumption for this field).
- `rom` specifies that the relocatable object module produced by the compilation is to be directed to a specified file (fid), a logical device stream (stream-id), the card punch (CP), or no file or device (NO). If no rom specification is given, output is directed to a special file that may subsequently be referenced by a dollar sign.
- list specifies the destination of source-listing output: either a disk file (fid), a logical device stream (stream-id), the terminal (ME), central-site line printer (LP), or no file or device (NO).

Note that the ON or OVER qualifier refers only to the rom, but one of the two must be given if either rom or list is specified. For example: FORT4 ME ON, LISTFIL.

This command, then, serves to call FORT4, identify the input source, and direct the compiler outputs.

Note that you can direct the compiler outputs prior to giving the FORT4 command with the IOUTPUT, ILIST, and ICOMMENT commands (the latter allows a separation of source-listing and error-commentary destination). If the OUTPUT command is used, the default value for the rom given above does not apply.
After the FORT4 command, the processor responds with the question OPTIONS>, at which point you may enter one or more compilation options. These control the compilation process and are used primarily to request optional outputs or suppress standard outputs. The options controlling listing of outputs are:

- **LS** - Produce source-program listing and full compilation summary.
- **LO** - Produce source- and object-program listing, and full compilation summary.
- **PS** - Produce partial instead of full compilation summary (default option).
- **NS** - Suppress compilation summary.

Note that if none of the above are specified, a partial summary only is produced, as if the PS option were specified. The PS or NS option can be used in conjunction with LS or LO, or NS alone may be specified (no listing, no summary). If you use the LS or LO option, a destination for this output must be specified in the FORT4 command.

There are many other options, mostly having to do with the nature of the source input and the object output. These are described in the CP-V/TS Reference Manual, 90 09 07, and the FORTRAN IV/OPS Reference Manual, 90 11 43.

If you enter source lines directly from the terminal (i.e., FORT4 ME ...), you may want to use the SO option, which requests that the source program be reproduced as an output; in this case you must assign this output (the MS:SO DCB) to a file with a !SET command (see Chapter 11, "DCB Assignments"). Several examples are given below.

Following a successful compilation, link-loading and execution of the resulting object program can be requested with the !RUN command. This command, as well as the related !LINK and !START commands are described in Chapter 6, "Loading and Executing Object Programs". Simple uses of !RUN are shown in the following examples.

In the following example, the user employs Edit to create a file, INPUT, containing the source program. Note that the source lines contain a tab character: for FORT4, only one tab per line is accepted, and its value is fixed by the compiler as column 7 (regardless of specified setting). The example program computes the length of a three-dimensional vector, D, for input values of X, Y, and Z. Execution-time input to the program is initially from file DATA; input is terminated by a zero value for X. Output is initially directed to the terminal.

The user then decides to execute again with new X, Y, and Z values from the terminal. Accordingly, he changes the DCB assignments for FORTRAN I/O units 5 and 6 so that data input is from the terminal and program output goes to the disk file VALUES. To examine this output, he issues a ICOPY command to copy this file to the terminal.

Example 24. Compiling and Executing FORTRAN Input from a File

```
!TABS 7 

The user sets a tab value of 7, so that he can see the tab effect as he builds the file.

!BUILD INPUT

1.000 WRITE (6,100)
2.000 READ (5,200) X,Y,Z
3.000 IF (X) 20,50,20
4.000 D = SQRT(X**2+Y**2+Z**2)
5.000 WRITE (6,300) X,Y,Z,D
6.000 GO TO 10
7.000 STOP
8.000 FORMAT (7X,11X,11X,11L1H,11L1H,11X,1HD)
9.000 FORMAT (3E)
1.000 FORMAT (4(1X,E11.3))
11.000 END

He builds a file of source input, named INPUT.
```
He builds a program-data file.

and requests error commentary at the terminal.

He asks for a compilation of INPUT, with ROM output on BIN.

and accepts the default option, partial summary.

The partial summary prints at the terminal.

The user assigns the file DATA to the F:5 DCB, and defines it as an input file. (This is a "file assignment").

He assigns the user's terminal to the F:6 DCB, via the operational label UC. (This is a "device assignment").

He requests a run, i.e., link-load and execution, of the program. Since the RUN command assumes as its input the results of the latest compilation or assembly if no input file is specified, he does not need to specify BIN.

The loader's messages print.

Then the program's output appears, and a normal program-halt is indicated.

The user resets the input unit to the terminal.

and the output unit to a file, named OUTPUT.
He reruns, this time specifying the ROM name (not actually required in this case, as explained above).

The program-input-request prompt is given, and the user enters a set of values and a zero value to indicate end of data.

A normal program halt is indicated.

The user requests a copy of the output file to the terminal.

The next example shows a very simple program entered directly from the terminal. The user requests the source program to be reproduced (SO), and uses a !SET command to assign a source-output file, SOURCE. He also uses the !SET command to assign FORTRAN unit 6, the program output, to the terminal.

Example 25. Submitting Terminal Input for FORTRAN Compilation

The user sets the DCB for source output produced by the compiler, M:SO, to the file SOURCE. Here, since he does not specify a file function (e.g., IN, OUT), OUT is assumed by default.

This sequence will cause the FORT4 prompt character (>) to be excluded as part of the input line when tabbing. The backslash prints automatically as a result of the \ C sequence.

He asks for a compilation of direct terminal input.

He suppresses the partial summary (NS), and requests source output (SO).

FORTRAN prompts for source input with >. Note that the C in the fifth line is in column 6, the rest following a tab starting in column 7. (The user assumes that the tab setting of 7 from the previous example is still in effect.)
The user turns off the tab relative mode.

```
.SET F:6 UC
```

He sets the output unit to the terminal (operational label UC).

```
.RUN
```

and requests a run.

```
LINKING $
PI ASSOCIATED
THIS IS A CONTINUED LINE.
*STOP* 0
```

```
COPY SOURCE TO ME
```

He displays the reproduced source file.

```
C THIS EXAMPLE ILLUSTRATES HOW SOURCE LINES ARE ENTERED
C DIRECTLY FROM THE TERMINAL, AND HOW A LINE IS CONTINUED.
WRITE (6,100)
100 FORMAT (lX,
  G25HTHIS IS A CONTINUED LINE.)
END
```

Note that the "to be continued" marker (;) in the fourth line has been stripped off by FORT4.

```
OFF
```

```
--accounting summary--
```

COBOL

COBOL (COmmon Business Oriented Language) is a language that is especially efficient in the processing of business problems. Such problems typically involve relatively little algebraic or logical processing. Instead, they most often manipulate large files of basically similar records in a relatively simple way. This means that COBOL mainly emphasizes the description and handling of data items and input/output records.

The COBOL compiler is called from an on-line terminal by the following command:

```
COBOL [source][ME][ON][OVER][rom][list]
```

where

- **source** specifies a disk file containing the source program.
- **ME** indicates source input from the user's terminal (the default assumption for this field).
- **ON** indicates that ROM output is to be on a new file.
- **OVER** indicates that ROM output is to be over an existing file or on a new file.
ROM specifies that the relocatable object module produced by the compilation is to be directed to a specified file (fid), a logical device stream (stream-id), the card punch (CP), or no file or device (NO). If no ROM specification is given, output is directed to a special file that may subsequently be referenced by a dollar sign.

LIST specifies that listing output is to go to a file (fid), a logical device stream (stream-id), a line printer (LP), the terminal (ME), or no device or file (NO).

When the compiler is entered, it sends a request for options to the terminal.

OPTIONS?

If no options are desired, a carriage return may be entered following the request. This initiates the compilation.

If compilation options are desired, the word COBOL must be entered followed by the codes for the desired options. These codes are separated by commas and terminated by a carriage return or line feed character which initiates the compilation. A few of the options that are available are:

- GO - Specifies that a load-and-go copy of the object program is to be written via M:GO.
- LO - Requests an object program listing via M:LO.
- LS - Requests a source program listing via M:LO.
- SO - Requests source output via M:SO.

Example 26 shows how to build and execute a COBOL program using the COBOL compiler.

Example 26. Building and Executing a COBOL Program

ITABS 9,13 @)

The user sets the simulated tab stops for his terminal to columns 9 and 13. Since the COBOL prompt character will print in column 1 of his terminal, COBOL will interpret these tabs as being set in 8 and 12.

SET M:SO DC/SOURCE @)

The user wants the source output file (SO) to be named SOURCE.

COBOL ME ON ROM @)

The user calls the COBOL compiler and specifies that source input is to be read from the terminal.

COBO COBOL

OPTIONS?

The compiler identifies itself and requests compiler options.

$COBOL GO, SO @)

The user enters a COBOL control command, specifying that he wants source output and a load-and-go copy of the object program.

$ IDENTIFICATION DIVISION.@)
$ PROGRAM-ID. SIMPLE.@)
$ DATA DIVISION.@)
$ PROCEDURE DIVISION.@)
$ PARA-L. DISPLAY 'A.O.K' UPON PRINTER.@)
$ STOP RUN.@)
$
The programmer enters a COBOL program and then enters ESCAPE F to indicate that the program is ready for compilation. The program is compiled and the following diagnostic message is output:

```
***NUMBER OF DIAGNOSTIC MESSAGES 0***HIGHEST
SEVERITY LEVEL 0***
```

```
/RUN ROM(NL)(NP) OVER LMN; BLIB:.COBLIB @
```

Since there were no errors in the program, the user decides to execute it. The RUN command specifies that an executable load module named LMN is to be built using the object module named ROM, no public libraries or core libraries are to be searched, the BLIB: library in the COBLIB account is to be used to satisfy any external references, and the load module is to be executed.

```
LINKING ROM
LINKING BLIB:
A.O.K.
```

The message A.O.K. is printed on the terminal because the terminal is the default LO device when COBOL is run in the on-line mode.

---

**META-SYMBOL (META)**

Meta-Symbol is a macro-assembler that processes an assembly language, Symbol, (which is a symbolic representation of the machine language) and macro-procedure language, Meta-Symbol (which is a powerful logical extension of the assembly language). Assembly language is the "lowest level" language normally used for programming.

The advantage of Meta-Symbol programming is the maximum speed and efficiency that is possible in the resultant object programs. Its disadvantage is that it is more time-consuming to learn and to use than "higher-level" languages such as FORTRAN.

Also available is an extensive and sophisticated debugging processor, Delta, designed specifically – though not exclusively – for debugging Meta-Symbol object programs. Its use is covered in Chapter 7 and in Example 47.

The META processor is called by the TEL command META. There are many examples throughout the following chapters that illustrate the use of META:

Example 38 shows an assembly and execution.

Example 43 shows use of OUTPUT, LIST, and COMMENT commands.

Example 44 shows use of SET commands before calling META.

Example 45 shows discontinuation and resumption of output while assembling with META.

These examples all illustrate the use of META to assemble from a source file. META can also be used to assemble source lines directly from the terminal, as shown in the following example. Unlike the FORT4 processor however, diagnostics are not produced until after the END statement is received. ("Diagnostic" is a general term for the warning and error commentaries resulting from the error checking performed by the assembler.)
The format of the META command is

```
META [source] [ME] [ON] [OVER] [rom] [list]
```

where

- **source** specifies a disk file containing the source program.
- **ME** indicates source input from the terminal (the default assumption for this field).
- **rom** specifies that the relocatable object module produced by the assembly is to be directed to a specified file (fid), a logical device stream (stream-id), the card punch (CP), or no file or device (NO). If no rom specification is given, output is directed to a special file that may subsequently be referenced by a dollar sign.
- **list** specifies the destination of the source-program listing: either a disk file (fid), a logical device stream (stream-id), the terminal (ME), the line printer (LP), or no device or file (NO).

Note that the **ON** or **OVER** qualifier refers only to the rom file, but one of the two must be given if either rom or list is specified.

The effect of the META command variable field is to assign the **M:SI** (source input) DCB, the **M:GO** ("go", or object output) DCB, and the **M:LO** (listing output) DCB to the source, rom, and list specifications, or to their defaults. Note also that if these DCBs have been assigned previously in the session, either by an OUTPUT, LIST, FORT4, or prior META command, the corresponding default values given above do not apply. (The effect of the COMMENT command is to explicitly assign the **M:DO** (diagnostic output) DCB; i.e., to specify a destination for diagnostics separate from the source listing, if any.)

After the META command is given, the processor asks for assembly options: **WITH**. A description of these options for on-line usage can be found in the CP-V/TS Reference Manual, 90 09 07, Chapter 4. The only options we need mention here are **SO** (source output), which functions exactly as in a FORTRAN compilation - shown in the previous section - and **SD** (symbolic-debugging), which is covered in Chapter 7. Note that source-listing output is implicitly requested or suppressed by the list parameter in the META command, unless a LIST command is given before the META command.

Note also that the format of the assembler source listing is not very suitable for display at the terminal, and is best directed to the line printer (LP), or omitted. Comments go to the terminal (by default) in either case.

**Example 27. Using META to Assemble Terminal Input**

```
META ME

The user asks for an assembly of terminal input, with no source listing.

WITH

He doesn't request any assembly options and, below, begins to type in the source lines following META's prompt character (>). (A tab setting and tab characters could be used to achieve the desired starting columns as shown in later examples.)
```

```
2*THIS EXAMPLE ILLUSTRATES DIRECT INPUT FROM TERMINAL.
2*IT ALSO SHOWS HOW TO CONTINUE A LINE.
> SYSTEM RPM
> SYSTEM SIG7
> REF M:UC
>START M:WRITE M:UC,(BUF,M; (CONTINUED LINE)
```
Here the library-search option NP is used to suppress association of the default public library, P1, by the loader, as it is only required for FORTRAN programs.

**Example of continued line.**

The program executes, printing its output, and control returns to TEL.

Example 28. Using APL in the Desk Calculator Mode

The user identifies the 2741 terminal to the system.

```
XEROX CP-V AT YOUR SERVICE
ON AT 10:16 MAY 16, '73
LOGON PLEASE: 2466, SMITH

The CP-V system identifies itself and the user logs on.
```

Example 28 provides an example of logging on to CP-V with an APL terminal, calling APL, using APL in the Desk Calculator Mode, and logging off. In Example 29, APL is used in the Function Definition Mode and the Function Editing Mode.
Note that TEL prompts with a ◆ character at an APL terminal. The user calls APL and APL acknowledges control and prints the workspace status.

456+2095+74 ◆

The user begins using APL in the Desk Calculator Mode by adding three numbers together. Note that APL provides the indentation but does not use a prompt character.

L05*.5 ◆
UNDEFINED
L05*0.5 ◆
A

The user then unsuccessfully attempts to take the square root of 105.

105*.5 ◆
10.24695077

The square root operation is now successful.

6 15 8 495 *2 ◆
36 225 64 245025

In the above operation, the user requests the square of the numbers 6, 15, 8, and 495.

)OFF ◆

CPU = .0069 CON= :08 INT = 13 CHG = 0

The user logs off from both APL and CP-V. If the command had been )OFF HOLD, the user would have been logged off from APL and control would have returned to TEL.

Example 29. Using APL in the Function Definition and Function Editing Modes

The user logs on and calls the APL processor.

△C=A HYP B ◆

He decides to define a function that will calculate the length of the hypotenuse of a right triangle, given the lengths of the two sides. The del (▼) character signals function definition and is followed by the function name.

[1] C + (A*2)+B*2)*0.5 ◆
[2] ▼ ◆

54 APL
The system responds with \[1\] and waits for the first program line. Each successive line is also numbered until the routine is closed by another \(\nu\). (The user could have closed the function by placing the \(\nu\) character at the end of line 1.)

\[
3 \text{ HYP 4 (}}
\]

\[
5
92 \text{ HYP 3 (}}
\]

\[
92.04890005
\]

The user tries a few examples.

\[
\text{VA GEOMETRY B (}}
\]

\[
[1] \ '\text{FUNCTION WRITTEN BY M. W. SMITH}' \]
\[
[2] \ '\text{GIVEN A RECTANGLE OF}' \]
\[
[3] \ '\text{SIZE } ';A'; \text{ BY } ';B' \]
\[
[4] \ '\text{PERIMETER: } ';A'+B \]
\[
[5] \ '\text{AREA: } ';A\times B' \]
\[
[6] \ '\text{DIAGONAL: } ';A\text{ HYP } B' \]

The user writes a second function—one to calculate the perimeter, area, and diagonal of a rectangle. Note that he makes use of the previously defined HYP function within this function. He also made a mistake which will later need to be corrected.

\[
10 \text{ GEOMETRY 12 (}}
\]

The user tries to use the GEOMETRY function and receives the printout listed below.

\[
\text{FUNCTION WRITTEN BY M. W. SMITH}
\]
\[
\text{GIVEN A RECTANGLE OF}
\]
\[
\text{SIZE 10 BY 12}
\]
\[
\text{PERIMETER: 22}
\]
\[
\text{AREA: 120}
\]
\[
\text{DIAGONAL: 15.62049935}
\]

After examining the printout, the user notes that the perimeter was not calculated correctly. The value should be twice the sum of the two sides.

\[
\text{GEOMETRY}[4022]\]

The user indicates that he would like to modify line 4 of the GEOMETRY function beginning at column 22.

\[
[4] \ '\text{PERIMETER: } ';A'+B
\]
\[
\text{/// (}}
\]
\[
[4] \ '\text{PERIMETER: } ';2\times A'+B' \]
\[
[5] \ \nu\]

APL types line 4, performs a carriage return and spaces to column 22. The user types three slashes indicating that he wants the characters in columns 22 through 24 deleted. APL then retypes the line and waits, allowing the user to add new characters to the line if he so desires. The user types in \(2\times A'+B\). APL responds with the next line number, allowing the user to perform further modification to the function if he so desires. The user has completed the modification that he planned and indicates this with a \(\nu\) character.

\[
10 \text{ GEOMETRY 12 (}}
\]

\[
\text{FUNCTION WRITTEN BY M. W. SMITH}
\]
\[
\text{GIVEN A RECTANGLE OF}
\]
\[
\text{SIZE 10 BY 12}
\]
\[
\text{PERIMETER: 44}
\]
\[
\text{AREA: 120}
\]
\[
\text{DIAGONAL: 15.62049935}
\]
The user tries the function again to see if it is working correctly and sees that it is. However, now he has second thoughts about the line that says "FUNCTION WRITTEN BY M. W. SMITH" and decides to delete that line.

`GEOMETRY[1]`  

He opens the function and directs the system to line 1.

`[1]`  

The system prompts with `[1]` and the user presses the ATTN key followed by the RETURN key.

`[2]`  

The user closes the function because no further editing is to be performed.

```
10 GEOMETRY 12  
GIVEN A RECTANGLE OF  
SIZE 10 BY 12  
PERIMETER: 44  
AREA: 120  
DIAGONAL: 15.62039935  
```

The user executes the function again and is pleased with the results. He lists the function definition for future reference, saves the 'workspace' containing HYP and GEOMETRY, and then logs off.

```
GEOMETRY[1]  
V A GEOMETRY  
[1] 'GIVEN A RECTANGLE OF '  
[2] 'SIZE ',A,' BY ',B  
[6] V  
  )SAVE MYMATH  
MYMATH Saved 10:00 MAY 17, '73  
)OFF  
```

In later sessions, the user can access HYP and GEOMETRY by using a )LOAD or )COPY command on the workspace named MYMATH which has been saved as a file.
6. LOADING AND EXECUTING OBJECT PROGRAMS

LINK PROCESSOR

The LINK processor consists of a one-pass link-editor/loader, or linking loader. The essential functions of the linking loader are to combine a number of separate program elements into a single executable entity called a load module (LM), and to load it for execution. You can request these two functions together with the RUN command, or separately with the LINK and START commands, respectively. In its linking operation, LINK merges internal symbol tables of several relocatable object modules (ROMs) presented to it and searches one or more subroutine libraries to satisfy external references, where required. It makes full use of the CP-V Sigma hardware memory-mapping, allocating virtual data space as needed for association of a public core library such as the FORTRAN P0 or P1 libraries.

The linking loader must be used both to link-edit and load one ROM, i.e., the output of one compilation or assembly, along with any necessary system-supplied service procedures and library subroutines, or to link two or more ROMs from separate compilations or assemblies, with their combined system-related references, into one load module.

RUN COMMAND

The TEL command RUN requests linking, loading, and executing of one or more ROMs. Forms of the RUN command are as follows:

1. RUN (or RUN $)

These forms simply request that the ROM created by the last compilation or assembly be linked, loaded, and executed. The two forms shown are synonymous. (Input is taken from the file last assigned to the $M; GO DCB; LM output is placed on a special temporary file.)

2. RUN rom

The ROM stored on the disk file specified by rom is to be linked, loaded, and executed. (LM output is placed on a special temporary file.)

3. RUN [rom] [ON OVER] Imn

ROM input may be specified as in 2, above, but the LM output may also be directed to the file named Imn.

In each case, the LM output is available for a subsequent reexecution via the START command. In all three cases, the public core library P1 is implicitly associated with the object program to satisfy any external references, if possible.

The general formats of the RUN and LINK commands are identical; thus the more complicated form shown for LINK in the next section is equally applicable to RUN, and vice versa.

Example 30. Using the RUN Command

```
.: EDIT 
EDIT HERE 
EDIT HERE 
TA M 

The user calls Edit.

He uses the Edit Tabs command (TA) and specifies the Meta-Symbol (M) tab setting (10, 19, and 37). (Other sets are available; see CP-V/TS Reference Manual, 90 09 07.) He then builds a source file, INPUT.
```
META is called to assemble source file INPUT with ROM output going to file BIN and no assembly listing produced.

WITH> 

No assembly options are desired.

RUN 

A run is requested from the last compilation/assembly output, i.e., BIN in this case.

LINKING §

The system acknowledges the LINK function (the LINK processor is implicitly called).

DEFAULT CORE LIBRARY IS NOT NEEDED

See Example 31 for meaning of this message.

THIS MESSAGE SHOULD PRINT AT THE TERMINAL.

The program's output is printed.

OFF 

The user logs off. The temporary file containing the load-module output of RUN is now lost. (The ROM file BIN is permanent, however.)

LINK COMMAND

The LINK command requests link-editing, as does RUN, but does not cause loading and execution of the resulting load module. A more complex variable-field format than those shown in the previous section for RUN is given here:

\[
\text{LINK } \left( \text{rom}_1, \ldots, \text{rom}_n \right) \oplus \left( \text{OVER} \text{lm}_n \right) \oplus \left( \text{lid}_1, \ldots, \text{lid}_n \right)
\]

where

- \text{rom}_i \quad \text{specifies a disk file containing a ROM.}
- \text{lm}_n \quad \text{specifies a disk file for the LM output.}
- \text{lid}_i \quad \text{specifies a disk file containing a user's subroutine-library.

In the format above, the several ROMs specified will be linked into one LM, with user's libraries \text{lid}_1 \text{trough \text{lid}_n} searched (prior to any public or system libraries) to satisfy external references, and the result placed ON or OVER \text{lm}_n if specified.
In addition to the above, a parenthesized library-search code may be given. It is conventionally placed after the command verb, as in LINK (code) . . . . These codes request or suppress searching of system-supplied libraries, and are listed in Appendix D. Also, internal symbol tables for several ROMs may be merged or selectively deleted in the load module (see the CP-V/TS Reference Manual, 90 09 07, for these formats).

Example 31. Using the LINK Command

```
1 LINK BIN ON LOAD NX
   A link-edit of the ROM on file BIN is requested, with the resultant LM placed on LOAD.

LINKING BIN
   The system responds to the LINK command.

DEFAULT CORE LIBRARY IS NOT NEEDED
   The absence of a library search code (see Appendix D) in the LINK command causes this message if the default library (P1) is not required. The specification of search code NP will suppress association of P1 and also suppress this message.

IOFF NX
   Since the user does not want to execute the program at this time, he logs off. Files BIN and LOAD are permanent and can be accessed in subsequent sessions.
```

START C

The START command can be used to load and execute a load module produced by a prior LINK command, or to reexecute an LM already RUN (or STARTed). Three forms are applicable:

1. START
   This form causes the last LM produced, either via a LINK or RUN, to be loaded and executed. Note that the prior LINK or RUN must have been given during the current terminal session; the load-module file may have been explicitly named (Imn), or named by default ($).

2. START $
   This form causes the last LM produced on the temporary file $ to be loaded and executed; the load-module file must have been named by default ($).

3. START Imn
   This form causes the load module contained on the specified file to be loaded and executed. The LM may have been the result of either a LINK or RUN operation.

   See Chapter 8, User Programs, for an alternate way of loading and executing user-developed object programs:

Example 32. Using the START Command

```
1 START LOAD NX
   The load module LOAD created in Example 31 is loaded into core and execution begun.
```
THIS MESSAGE SHOULD PRINT AT THE TERMINAL.

The program's output is printed.

loff

- accounting summary -
7. DEBUGGING USER PROGRAMS

Two dynamic debugging facilities are available for on-line use:

- Delta processor for debugging Meta-Symbol programs.
- FORTRAN Debug Package (FDP) for debugging Extended FORTRAN IV programs.

"Debugging" is a general term for program-error detection and correction; dynamic debugging implies that the debugging process is carried out during the execution of an assembled or compiled program (as opposed to "desk checking"). Both Delta and FDP allow symbolic, i.e., source-program level references to elements of the object program.

ASSEMBLY LANGUAGE DEBUGGING (DELTA)

Delta provides conversational debugging capability for checkout and modification of Meta-Symbol programs at execution time. Delta allows full use of symbolic references to elements of the object program, and enables you to

- Control program execution, i.e., stop and restart it at any point, by means of breakpoints that you may insert in the program at your discretion. These breakpoints may be unconditional ("always stop"), conditional ("stop under certain circumstances"), or based on changes in data values.
- Examine, modify, and insert various program elements: instructions, constants, variable values, and encoded data of all types and formats. This can be done both prior to execution and during any halt in execution (e.g., due to a breakpoint).
- Trace continuous program execution by requesting a repeated display of specified sets of related information: register contents, switches, data values, etc., at specified points in the program.
- Search programs and data for specific elements and values.

Delta may also be used to write and check short Meta-Symbol or machine language programs.

Please refer to the CP-V/TS Reference Manual, 90 09 07, for a comprehensive description and explanation of the commands available under Delta.

EXECUTING IN DEBUG MODE

To initiate execution of a program in debug mode, you must append the clause UNDER DELTA to your RUN or START command. Also, you must specify the SD (symbolic debugging) assembly option in response to WITH> to preserve the internal symbol table(s) of your program, if you want to refer to internal symbols with Delta commands — the normal case. (Internal symbols are those whose point of definition and points of use are entirely within one ROM.)

Note that the global (or external) symbols of your program are always available for reference (see the following section).

When UNDER DELTA has been specified, Delta intervenes between program loading and initial execution. At this point you can issue debugging commands to examine or modify locations, insert breakpoints, start execution at a specified point, etc. Delta also assumes control at any halt in execution.

The following example illustrates the usual method of using Delta in the debug mode of execution. A simple program is assembled with the SD option, run UNDER DELTA, and patched to create a missing M:EXIT statement. Note that before you refer to internal symbols you must tell Delta the name(s) of the desired symbol table(s) by ROM-file name (even though only one ROM may have been assembled).

To leave Delta and return to TEL, you issue a Y^C control combination.
Example 33. Assembling and Loading in the Debug Mode

iMETA ME ON BFILE
WITH SD

The user calls META to assemble statements from the terminal. He uses the SD option to cause an internal symbol table to be produced.

\$ SYSTEM SIG7
\$ SYSTEM BPM
\$ REF M:UC
\$BEGIN M:WRITE M:UC,(BUF,MES),(SIZE,9)
\$MES TEXT 'GREETINGS'
\$END BEGIN

* NO UNDEFINED SYMBOLS
* ERROR SEVERITY LEVEL: 0
* NO ERROR LINES

Although there are no assembly errors, the user notes that he forgot to include an M:EXIT in the program and decides to make this correction with patches.

!RUN BFILE UNDER DELTA (NP)

LINKING BFILE

He links and loads UNDER DELTA, suppressing loading of the default library with the code NP.

DELTA HERE

"ring"

Delta identifies itself and prompts with a ring of the console bell.

BFILE;S

The user selects the internal symbol table associated with ROM BFILE.

BEGIN/ CALL,1 MES+.3

This command opens the cell at location BEGIN and displays its contents.

BEGIN/ 410C004

A command is now entered to cause the contents of BEGIN to be displayed in hexadecimal format. The user terminates the command with the tab-key sequence, CONTROL I, which causes the cell addressed by this command (location C004) to be opened and displayed.

MES+.3/ 11008C3C
MES+.4/ 30000000
MES+.5/ C001
MES+.6/ .9

The contents of the function parameter table (FPT) referenced by the M:WRITE (at location BEGIN) are displayed. Note that location C004 is shown symbolically as MES+.3. A line feed causes the next cell to be opened and displayed. A carriage return terminates the sequence. Note that the hexadecimal conversion format is maintained over the and .

BEGIN/ B MES+20

The user issues a command to open the cell at BEGIN and enters a branch to location MES+20, a patch area he has chosen that is well beyond the main program and the FPT displayed above.
He enters symbolic code for the M:WRITE instruction (as originally contained in BEGIN, displayed above). The line feed causes the next cell to be opened for modification.

The next location prints with a hexadecimal displacement. He then enters symbolic code corresponding to an M:EXIT. He has now entered all his patches.

BEGIN;G

He initiates execution.

GREETINGS

EXIT AT MES+.15

The output message prints, and Delta reports execution of the M:EXIT, stating the location of the M:EXIT (MES+.15).

The user interrupts with YC and then logs off.

OFF

FINI

The system informs him that Delta was terminated.

- accounting summary -

USING DELTA IN NONDEBUG MODE

Delta may also be called for use when you have not initially executed in debug mode, i.e., you did not specify UNDER DELTA in your RUN or START command. The next example illustrates this type of usage.

Note that only the global symbol table is available, and that the user's first Delta command must be ;S to cause this symbol table — associated with the load module as a whole — to be loaded. Otherwise, no symbols will be available for reference. (If rom;S is specified, as was possible in the preceding example, the global table is loaded implicitly.)

Example 34. Calling Delta after Assembling and Executing in Nondebug Mode

The user wants to assemble lines from the terminal and to default all options.

!META ME

WITH> SYSTEM SIG7

≥ SYSTEM BPM

≥ DEF START

≥ REF M:UC

≥START LI,3 55

≥ M:STIMER (SEC,5),XY

≥AB LI,4 0

≥ STW,4 X
The user notes that the program is looping more than was intended, and notices that an error was made in the first statement (he typed 55 instead of 5), and decides to interrupt with YC and call Delta to enter a patch. (The system did not echo a left arrow since it was in output mode.)

DELTA

Control goes to TEL. The user calls the Delta processor.

DELTA HERE

"ring"

Delta identifies itself and prompts with a bell.

;S

The user loads the global symbol table. The only symbol that can be referred to is START which is the only DEF in the program.

START(X/ .22300037 .22300005)

He enters a Delta command to display the contents of START in hexadecimal format, and changes this value to the hexadecimal equivalent of LI, 3 5.

START;G

He directs execution to the beginning of the program (location START).
This time the program executes as was intended.

**EXIT AT START + .A**

Delta reports execution of the M:EXIT, i.e., normal termination.

**CONTROL and Y interrupts Delta and returns control to TEL.**

The user logs off.

---

**USING DELTA TO WRITE PROGRAMS**

The user may write and check short Meta-Symbol or machine language programs using Delta. Example 35 illustrates the method by which this is done. In the example, a table TAB with ten numeric entries is created and a program is written to find the sum of the numbers and to store the result in location SUM. It would be helpful to review the commands:

```
e\[K
```

and

```
e\{f <5 >[K
```

in Chapter 7 of the CP-V/TS Reference Manual, 90 09 07, before studying the example.

**Example 35. Using Delta to Write a Program**

__DELTA \(\odot\)___

**DELTA HERE**

```
.10000(X<TAB>K \(\odot\)
```

The user begins creating the data for his program by defining the global symbol TAB at location .10000. (The range of addresses available to the user is .A000 -.1BFF.)

**TAB\(5\) \(\odot\)**

The page at .10000 is obtained from the Monitor with the command TAB\(\). Also, the cell at .10000 is opened. The user then loads ten values into the table TAB, the first value being the 5 above.
The global symbol SUM is defined at the next available location.

```
TAB+.8 \( R < \text{BEGIN} > K \)
BEGIN \( \text{LI,2} \quad 0 \)
BEGIN+.1 \( \text{LI,3} \quad 0 \)
```

The global symbol BEGIN is defined at the next available location and the first two instructions of the program are written.

```
BEGIN+.2 \( R < \text{RETURN} > K \)
RETURN \( \text{AW,3} \quad \text{TAB,2} \)
RETURN+.1 \( \text{AI,2} \quad 1 \)
RETURN+.2 \( \text{CI,2} \quad 10 \)
RETURN+.3 \( \text{BNE \ RETURN} \)
RETURN+.4 \( \text{STW,3} \quad \text{SUM} \)
RETURN+.5 \( \text{CALL,9} \quad 1 \)
```

The global symbol RETURN is defined at the next available location and the remaining instructions of the program are written.

```
BEGIN;G
```

The user executes the program.

```
EXIT AT RETURN+.5
```

```
SUM/776
```

The user obtains the answer by displaying the contents of SUM.

**FORTRAN DEBUGGING (FDP)**

The FORTRAN Debug Package provides a powerful conversational facility for convenient and rapid checkout of FORTRAN IV programs. The debugging features provided are dynamically controllable from the terminal at program-execution time, and include the following:

- Statement stepping.
- Conditional breakpoints.
- Data-change breakpoints.
- Execution-flow tracing and event-history recording.
- Display and modification of scalar and array-element values.
- Branching.
- Program restart.
- Statement skipping and deletion.
- Automatic calling-argument display.
You may refer to variables by name and to statements by source-line number or statement label. These references may be further qualified by subprogram name.

The FDP facility consists of a sublibrary of run-time subroutines (a portion of public library P0), plus the necessary symbol tables and in-line coding generated by the compiler when debug-mode is requested. (FDP can be used only when debug-mode compilation has been performed.) Programs compiled in debug mode should not be used indiscriminately, as they require approximately 2.5 times the amount of memory required for nondebug runs and may even double normal execution times.

In order to use FDP, you must do the following:

1. Specify the DEBUG compilation option when FORT4 prompts for options.
2. Specify in the RUN or LINK command either one of the library-search options (FDP or P0), or the clause UNDER FDP (the three forms are synonymous).

The two examples given here illustrate, in addition to TEL command usage, some of the more commonly used FDP commands. See the FDP/Reference Manual, 90 16 77, for a complete description of the FDP commands, and a full explanation of their use.

In the following example, the user compiles file INPUT, created in a previous example, in debug mode. Values for X, Y, and Z are read from file DATA (also created in the prior example). The ON debugging command causes values of D, X, Y, and Z to be displayed whenever D is computed.

Example 36. Use of FDP ON and PRINT Commands

```
!FORT4 INPUT ON MODE

The user compiles file INPUT and directs the listing and compilation summary to the terminal.

EXT. FORTRAN IV, VERSION 000
OPTIONS >DEBUG,LS MODE

Note the specification of DEBUG as an option.

1: WRITE (6,100)
2: 10 READ (5,200) X, Y, Z
3: IF (X) 20,50,20

LOCAL VARIABLES (6 WORDS):

00000 X     00001 Y     00002 Z     00003 D
```
The program listing and compilation summary is printed.

`SET F:6 /VECTORS;OUT` 

The user directs the program output to file VECTORS.

`SET F:5 /DATA;IN` 

Program input will be read from file DATA.

`RUN (FDP)` 

The user loads and executes in the debug mode. Alternatively he could have specified:

- `RUN UNDER FDP`
- `RUN (PO)`

`LINKING` 

The loader's message prints.

`@ON D;PRINT X,Y,Z` 

FDP prompts with @. The user enters commands to cause the value for D to be displayed each time it is stored into, and at the same time to display values for X, Y, and Z.

`GO` 

The user does not want to enter any more debug commands at this point and issues a GO command to start execution.

```
/4(20S): D=3.74166  X=1.00000
Y=2.00000
Z=3.00000
```
Values for D, X, Y, and Z are displayed. The slash (/) indicates main program and is followed by line number and statement number (if present) in parentheses.

*STOP* 0

This message is produced by the library subroutine STOP.

7(SOS): RDY TO STOP

This message is produced by the debugger.

QUIT

The QUIT command causes return to the monitor.

OFF

- accounting summary -

In the next example, the user enters a FORTRAN source program from the terminal without initializing variables, setting loop control, and providing for I/O. He runs in the debug mode and issues FDP commands to provide the omitted functions.

This program generates a Fibonacci sequence, in which the value of any number (beyond the second) in the sequence is equal to the sum of the values of the two preceding numbers, e.g., 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, ....

Example 37. Further Uses of FDP Commands

...
@STOP AT 3#5 @)

This command causes execution to halt the fifth time that statement 3 (the GO TO statement) is encountered.

@GO @)

Execution is now begun with the above commands in effect.

/l(10S): I=1
2(20S): J=2
1(10S): I=3
2(20S): J=5
1(10S): I=8
2(20S): J=13
1(10S): I=21
2(20S): J=34
1(10S): I=55
2(20S): J=89

Values for I and J are displayed. The slash (/) indicates main program and is followed by line number and statement number (in parentheses).

3(30S):

The program halts the fifth time that statement 3 is reached.

@KILL @)

FDP prompts for a command. This KILL cancels all previous FDP commands.

@STOP ON I>500 @)

A conditional stop, or breakpoint, is set.

@AT 3; PRINT I,J @)

These commands will cause values of I and J to print each time statement 3 is reached.

@RESTART @)

This specifies restart of program from beginning.

@GO @)

The user resumes execution.

/l(10S): I=144
J=233
3(30S): I=377
J=610

Values for I and J are displayed each time statement 3 is reached.

1(10S): I=987

At statement 1, the value for I exceeds 500 and the program halts.

@KILL ON I @)

This command cancels the last ON I, effectively the last STOP command issued.

@STOP ON J>10000 @)

Another conditional stop is issued.
Execution is resumed at statement 3, which is where the previous stop occurred.

/3(30S): I=987
J=1597
3(30S): I=2584
J=4181
2(20S): J=10946

Values for I and J print until J exceeds 10000 which occurs at statement 2.

@PRINT I
I=6765

Since statement 3 was not reached to cause the current value for I to be displayed, the user gives a PRINT command to cause this value to print.

@QUIT

The user now leaves FDP and returns to TEL.

LOFF

- accounting summary -
8. EXECUTING USER PROGRAMS

An object program stored on a file in load-module form may be called by its load-module name (lmn) used as a TEL command verb. The load-module file may be stored either in your own account, someone else's account, or the system account. Thus far, the lmn-as-verb command is synonymous to the ISTART lmn command (except for a difference in account-number defaults). Within the lmn command, however, you can also very conveniently make file or device assignments for three standard system DCBs: M:SI, M:GO, and M:LO.

The format of the variable field of the command is analogous to that of the FORT4 and META commands; the full format is

```
llmn [input] [ON] [OVER] [output_1] [, output_2]
```

where

- `llmn` is the fid of an LM that can take the full form:
  - `name [(account) (.password)]`
  - (see below for special defaults)
- `input` may be a fid or ME to be assigned to the input DCB M:SI.
- `output_1` may be a fid to be assigned to the output DCB M:GO.
- `output_2` may be a fid, ME, or LP to be assigned to the output DCB M:LO.

(Normal default assignments apply. That is, the M:SI and M:LO DCBs, if referenced, default to the user's terminal, and M:GO to a temporary file named $.)

The called program must, of course, directly or indirectly utilize one or more of the above-mentioned DCBs for any of these assignments to make sense.

You can imply or specify the account number under which the LM file is stored, and specify a password, as follows:

1. `filename` (alone, with no period) implies the system account.
2. `filename.` implies your account (i.e., the log-on account value).
3. `filename.account` specifies an account number.
4. `filename.account.password` specifies an account number and password.
5. `filename..password` implies your account and a password.

Note that this particular convention of default account number values is not the standard one that applies to most fid specification in TEL and other commands, as described in Appendix B. The reason for the system account default in particular is that installations may want to include, at system generation time, certain user-developed "production" programs in the system account; special forms of these may then be accorded preferential disk-storage and loading, depending upon frequency of use and programming characteristics. (META and FORT4 commands, for example, are actually special instances of lmn commands.)

The two examples following show very simple programs, developed wholly within the example for purposes of illustration. Actual uses of the command may, of course, call a program developed some time in the past, and possibly by another programmer.

The program in Example 38 reads a Meta-Symbol source program via M:SI, and writes out any comment lines (asterisk in column 1) contained in the program via M:LO. The input file and output device are assigned within the calling command. As a test, the user specifies as input the source program from which the called object-program was assembled.

Example 39 merely shows a simple FORTRAN IV program call by its load-module name. Since the compiler automatically provides (indirectly) program-file DCBs identified with names of the form F:n, file/device assignments cannot also be made within the lmn command for FORTRAN object programs.
Example 38. Using Load-Module-Name as Command Verb (Meta-Symbol Program)

*BUILD SOURCE

1.000 * ***UTILITY PROGRAM "EXTRACT"***
2.000 * THIS ROUTINE LISTS ONLY THE COMMENTS LINES, IF ANY, FROM

!META SOURCE

WITH (NO ERROR SEVERITY LEVEL: 0 NO ERROR LINES)

LINK (NP) ON EXTRACT
The user copies the source file using the NC option to strip the carriage-return off each record; otherwise the output below would be double spaced.

Here he calls the LM EXTRACT, with a following period to indicate "my account", and assigns the input file, SORCNC, and directs M:LO output to the terminal.

例

Example 39. Using Load-Module-Name as Command Verb (FORTRAN Program)

The user sets a tab stop for terminal input.
FORT4 is called to compile source program FILE1, with ROM output going to OUTFILE.

EXT. FORTRAN IV, VERSION CO2

OPTIONS=NS

FORT4 prompts for options. The user suppresses the partial-summary output.

SET F:6 UC

This command will cause output to device 6 to be directed to the terminal.

LINK OUTFILE ON POW3

Call LINK to create load module POW3.

LINKING OUTFILE

The LINK processor responds.

POW3 ASSOCIATED

Load module POW3 is loaded into core and executed. The log-on account is used.

--accounting summary--
9. GETTING IN AND OUT OF PROCESSORS

GENERAL

Once having logged on, you are always in one of three states of processing:

1. In a Job Step: You are in a system (or user) processor, i.e., in "normal" user-program execution.
2. In an Interrupt of a Step: You are at TEL level but have an interrupted processor associated.
3. Between Steps: You are at TEL level with no processor associated.

If you are in a processor, you can return control to TEL by depressing certain terminal keys (discussed shortly). Certain TEL commands can then be issued to perform minor operations after which control can be returned to the processor that was interrupted. The issuance of other TEL commands will cause either an abort of the previous job step or a diagnostic message. For example, interrupting META to issue a DONT COMMENT command does not cause an abort and allows return of control to META; interrupting META to call Edit will result in an abort of META; interrupting META to issue a SET command will result in the message "QUIT?", at which point the user may choose between quitting or continuing the META processor. A complete description of the TEL commands and their effect when used during a job step interrupt is given in Chapter 3 of the CP-V/TS Reference Manual, 90 09 07.

BREAK, CONTROL Y, ESC Y, AND ESC ESC

Any CP-V processor or user's object program can be interrupted by depressing the BREAK key. Use of the BREAK causes one of the following to occur:

1. If you are in a processor that has no command language (e.g., assembling with META), control is given to TEL whenever a convenient interrupt point is reached. TEL then prompts for a command.
2. If you are in communication with a processor that has break control (e.g., Edit, BASIC), and in a subprocess such as listing or copying, control is given to the processor, which prompts for its next command or possibly issues an interrupt message.
3. If an object program or processor is in a process that does not have break control (i.e., has not used the M:INT Monitor service) control is given to TEL.

The CONTROL Y combination or the ESC Y or ESC ESC sequences always return control to TEL. This type of interrupt can also be caused by depressing the BREAK key more than three times. (Certain processors may take special action on receipt of two or three break signals.) Examples of interrupting a processor are given in Example 40.

Example 40. Using CONTROL Y and the BREAK Key

```
  
  EDIT FILES @

  EDIT HERE

  The user decides to make changes to FILES.

  *IN 7,1 @
  7,000 Y @

  He starts to modify the file but changes his mind and interrupts by hitting CONTROL and Y simultaneously. The system echoes a left arrow.

  ^PCL @

  Control returns to TEL. The user calls PCL.
```
PCL identifies itself.

The user asks to have the names of the files that are currently in his disk directory listed.

He does not want to see the entire list, so he hits BREAK to stop the output.

Return is made to the command state of PCL. The user issues a COPY command to copy file FILES to the line printer.

He leaves PCL.

He calls Edit and issues commands to type lines in file FILES.

He does not want to see the entire file, so he returns to TEL by hitting BREAK four times. He could also have returned to TEL by depressing CONTROL and Y or @ @.

The Edit processor has break control and types this message in response to the first break. The subsequent breaks cause direct return to TEL.
QUIT AND CONTINUE Commands

After you have interrupted a processor and have optionally issued one or more commands, you have three alternative courses of action if the interrupted processor has not been aborted during the interrupt:

1. Return to the interrupted processor by issuing a CONTINUE command.
2. Discontinue use of the current processor by issuing a QUIT command.
3. Call another processor, which has the effect of aborting the previous operation.

Each of these actions is illustrated in the following example.

Note that both END and STOP are equivalent to QUIT, and that GO is equivalent to CONTINUE.

Example 41. Interrupting, Continuing, and Quitting Execution

```
1.BUILD INPUT
1.000 SYSTEM Y

The user wishes to build file INPUT but forgot to set tab stops before building the file. So he now interrupts Edit by simultaneously depressing CONTROL and Y which the system echoes as a left arrow. Control is given to TEL.

1.TABS 10,19,37

He now sets tab stops for the terminal I/O.

1.CONTINUE

He issues a CONTINUE command which takes him back to Edit (with no prompt). He retypes his first line, since he interrupted while typing this line.

2.000 SYSTEM SIG7
2.000 SYSTEM BPM
3.000 START:PRINT (MESS,MES)
4.000 M:EXIT
5.000 MES TEXT 'MESSAGE TO TERMINAL'
6.000 END START
7.000 META INPUT ON BFILE,LP

He calls META to assemble the program, but then spots an error in the program and interrupts with Y.

1.EDIT

He calls Edit to correct the error. META is automatically aborted.

EDIT HERE
*EDIT INPUT

He wants to retype line 5 to change TEXT to TEXTC.
```
He issues an insert command (IN) to correct the line. (Note that a space is not required between the command and the line number.)

```
5.000 MES TEXT 'MESSAGE TO TERMINAL'
*END
META INPUT OVER BOFILE, LIST
```

He again calls META to assemble file INPUT and request an output listing. Note use of OVER to reset file extension, ensuring that any output from the previous aborted assembly is overwritten.

```
*NO UNDEFINED SYMBOLS
*ERROR SEVERITY LEVEL:0
*NO ERROR LINES
!LINK (NP) BOFILE ON MES
```

LINK is called to create load module MES.

```
EDIT INPUT
```

EDIT HERE

```
*TYI-6
```

He now wishes to see the corrected source and calls Edit to display the file. (Note that a space is not required between the command and the line number.)

```
1.000 SYSTEM SIG7
2.000 SYSTEM BPM
```

He decides he does not want to see the entire file after all, so he simultaneously depresses CONTROL and Y to interrupt Edit and return control to TEL. The system did not echo a left arrow since it was in the output mode.

```
QUIT
```

He then issues a QUIT command so that use of the Edit processor will be discontinued.

```
INES
```

He now wants to load and execute program MES (but misspells the program name).

```
```

He realizes that MES is misspelled and that NES (which happens to be another valid program name) is now operating, so he returns control to TEL and types in the correct name.
The system informs him that the program cannot be loaded without quitting the previous process (NES), and that he must issue either a QUIT or a CONTINUE command. An implied QUIT may be issued by entering a RETURN or LINE FEED character by itself. (This message would not have appeared had the user preceded the MES. command with a QUIT command.)

The implied QUIT command causes the processor previously specified (MES) to be loaded and executed.

MESSAGE TO TERMINAL

The program output prints.

- accounting summary -

PROGRAM ABORTS

Many conditions can cause your program to be aborted, e.g., an invalid operation code. When an abort occurs, the system prints an abnormal or error code (e.g., 4A00) followed by a message telling you the reason for the abort. The CP-V/TS Reference Manual, 90 09 07, Appendix B, contains listings and explanations of the Monitor error messages.

The following example shows a program that will simply read two records of predetermined size from a file and print them at the terminal. However, a misspelled label in line 8 (BUF instead of BUFF – not a syntax error) causes an attempt at execution time to read into relative location 12. Since this location is in a write-protected procedure area of the program (i.e., the area cannot be stored into), the program is aborted and an appropriate message issued by the system. (Note that the program in this example is not intended to be realistic, but is designed solely to illustrate as simply as possible the “bug”, and thereby the point of the example.)

Example 42. System Handling of an Abort during Execution

The user builds files READ and LINES (following line 14).

1.000 SYSTEM SIG7
2.000 SYSTEM BPM
3.000 REF M:SI
4.000 REF M:UC
5.000 BUF EQU 10
6.000 START M:READ M:SI,(BUF,BUFF),(SIZE,16)
7.000 M:WRITE M:UC,(BUF,BUFF),(SIZE,17)
He calls META to assemble the source file. META produces summary messages indicating that there was an assembly error. However, the user decides to run the program anyway.

He sets M:SI to the input file.

The first record is written.

The system returns an abort message with an error code when the user tries to read the second record into location 12, which is in a protected area.
10. ASSIGNING DCBs

DATA CONTROL BLOCKS

A data control block (DCB) is a standardized table of information about the characteristics of an existent data-file or one to be created. The system's file-management service routines use the DCBs essentially to obtain detailed information both about the file, (i.e., the data) and the physical storage media assigned to it. This, combined with information supplied in a given service request, completely defines the requested operation. These routines also use the DCB to post or update dynamically-variable "historical" information concerning the data file (specific results of the last I/O operation performed, for example) to which the user's program and other system routines may refer.

The DCB also is, effectively, the connecting link between the user's input/output service requests, file-management commands, etc., and the actual disk storage space or peripheral device from which or on which a given data file is to be read, written, copied, saved, deleted, and so on. Sometimes the reference to this "link" is explicit at the user's level, as for example in an M:READ or M:WRITE Monitor procedure in a Meta-Symbol program, or in a SET command when the user needs to assign or reassign program input or output DCBs to specific disk files or devices.

MEANS OF FILE/DEVICE ASSIGNMENT

The ISET command may be used to explicitly assign any DCB (excepting M:UC, M:OC, and M:XX) to a file or device, as seen in a number of preceding examples. (SET can also be used for setting and resetting various parameters, or relatively fixed items of information in a DCB, e.g., file options, but a general discussion of this usage does not concern us here.)

The IOUTPUT, ILIST, and ICOMMENT commands can be used to implicitly assign several standard system DCBs commonly used by system processors: M:GO, M:LO, and M:DO, respectively. Usage of these commands was also shown and described for specific cases in preceding chapters. And, summarizing topics covered in Chapters 5 and 8, the source, rom, and list parameters of META, FORT4, and lm-name commands implicitly assign the M:SI, M:GO, and M:LO DCBs.

In general, the SET command need only be used to assign user-program files for DCBs that have no default assignment (or an undesired one), or to assign standard system DCBs, other than the ones named above, for special-option processor outputs, e.g., the CO, BO, and SO options and the corresponding M:CO, M:BO, and M:SO DCBs. To assign M:SI, M:GO, M:LO, and M:DO, the choice between the several means described above is simply a matter of the user's convenience, as they each do the same job, excepting that SET cannot be used in a job-step interruption. (See SET Command below, for specific information concerning BASIC.)

STANDARD SYSTEM DCBs

The system includes an extensive set of standard DCBs that provide for the majority of system- and user-program needs. The link-loader supplies a uniform loader-constructed copy of these DCBs to the user's program as required to satisfy references thereto. These DCBs all have names of the form M:xy, where xy generally corresponds to a system-defined operational label (discussed under SET Command below). These DCBs, when used on-line, have the on-line default assignment (if any) defined by the system for the corresponding operational label. Note that the default assignments for M:UC and M:OC, the user's terminal in both cases, are really fixed assignments, i.e., you cannot change them. (The default assignments can vary with individual installations, and most of them differ for batch operations.)

Although a number of system DCBs default to the user's terminal, the M:UC DCB is unique because (1) its fixed assignment is to the terminal — like M:OC, and (2) output through it is treated differently by the Monitor than output to the terminal via any other DCB — unlike M:OC. For terminal output via any DCB other than M:UC, the Monitor's COC (Character-Oriented Communications) routines automatically append a carriage-return/line-feed combination to each record written without a terminating carriage return. The COC routines do not append such a combination to output written via M:UC; it will substitute that character combination, however, for any carriage-return or line-feed character in the record. This difference allows you, when using M:UC, to produce one physical line at the terminal with a series of records. (See CP-V/TS Reference Manual, 90 09 07, Chapter 10, for details.)
In addition to the standard system DCBs, the link-loader will supply a uniform loader-constructed DCB for any M:ab DCB reference where M:ab is not known to the system, and for any DCB reference of the form F:ab, such as produced by FORTRAN IV for program files, where ab corresponds to the FORTRAN unit number. In these cases, the DCBs neither have a default assignment nor are they automatically defined for input or output — excepting F:101 through F:108, the FORTRAN standard units. They are also not defined for final disposition, and an I/O function and disposition parameter (e.g., IN, SAVE) may need to be set as well if the assignment is to a file or labeled tape. (These settings are described below.)

ASSIGN/MERGE TABLE

DCB assignments, excepting those for M:SI, automatically remain in effect across job steps until reset or negated. Assignments can be reset or negated between job steps. The mechanism for setting and resetting assignments is the assign/merge table, during an on-line session. An M:SI assignment is effective only for a single job step; following that step it always reverts to its default assignment, the user's terminal.

Any assignment made by any of the means described above causes an entry to be made in your assign/merge table. At the beginning of any job step involving a processor (including LINK) or a user's program, the entries in the assign/merge table are merged into the corresponding DCBs. (An entry in the table is deleted by a SET dcb 0.)

If an error occurs when accessing the ASSIGN/MERGE record, the user will be logged off. He must log back into the system to continue.

The apparent negation of an assignment achieved specifically by means of a DONT... command, e.g., DONT LIST, bypasses the assign/merge table and affects only a switch in the user's JIT (job information table) at the time the command is issued, whether between job steps or during a job-step interruption. (The implied DCB is not affected.) Only the standard processor outputs written via M:GO (OUTPUT), M:LO (LIST, and M:DO (COMMENT) DCBs can be affected in this way.

OUTPUT, LIST, AND COMMENT COMMANDS

Control over output from META, or FORT4, or a standardized user-processor may be exercised with the following commands before the processor command is issued:

- OUTPUT ON or OUTPUT OVER followed by a file name. This command specifies the destination of the relocatable-object output (ROM) from the processor via the M:GO DCB. M:GO defaults to a special file, which you may refer to in some cases with a dollar sign ($).

- LIST ON or LIST OVER followed by ME, LP, or file names. This command specifies the destination of the listing output from the processor, via the M:LO DCB. For META and FORT4, M:LO effectively has no default assignment. Either an explicit assignment must be made or the LIST command given to turn on the LO-output switch in the user's JIT. Apart from META and FORT4, M:LO defaults to the terminal.

- COMMENT ON or COMMENT OVER followed by ME, LP, or file name. This command specifies the destination of error commentary from the processor, via the M:DO DCB. M:DO defaults to the user's terminal. Therefore, COMMENT need not be used unless you want to direct error commentary to a destination other than your terminal.

In the following example, we specify destination files for the META output by using the LIST and OUTPUT commands, and (for purposes of illustration only) turn off the diagnostic output. We then assemble and execute the subprogram, but trap. We do not detect any errors in the source program, so in order to find out if we have assembly errors (which do show on the listing, however) we issue a COMMENT command to turn error commentary back on. We reassemble, find that we have a syntax error, and correct the line before reassembling again.

Example 43. Controlling the Destination of Processor Output

<p>| | |</p>

</tbody>
</table>
Before calling META, the user directs listing output to file LOFILE.

He specifies that the ROM output is to go to file BIN.

He overconfidently turns off error commentary.

He requests load module output on file CNTR100.

An abort message prints indicating the program would not execute properly.

The user does not spot any errors in the source, so he issues a COMMENT command to cause error commentary from META to appear at the terminal.

He calls META again. Files BIN and LOFILE were created when META was previously called, so they must be respecified in order to be recreated or written over, rather than extended. This time the error commentary prints at the terminal and indicates that statement 4 is in error.

He wants to change line 4 and uses the Insert (IN) command to enter a corrected statement.
He calls META again. Error commentary will still be directed to the terminal, since the previous COMMENT command is still in effect.

*NO UNDEFINED SYMBOLS

*ERROR SEVERITY LEVEL: 0

*NO ERROR LINES

**RUN (NP) BIN OVER CNTR100**

**LINKING BIN**

Since there are no errors in the assembly, he reloads and reexecutes the program, to recheck and get an updated load module.

Normal execution is indicated by a return to TEL with no message.

**OFF**

- accounting summary -

**SET COMMAND**

The general form of the ISET command is given in the CP-V/TS Reference Manual, 90 09 07, with descriptions of its many options and varied examples of its use. It is a complex command. Several forms, selected for particular uses, are as follows:

- To Assign a public disk File

  SET dcb /fid[filopt...]filopt]

where

filopt is one of the file-option parameters given in Appendix C, Table C-3. Some of these are

  \[\begin{array}{l}
  \text{IN}[[\text{SHARE}]] \quad \text{DEXCL} \quad \text{EXCL} \quad \text{function} \\
  \text{OUT} \quad \text{OUT} \quad \text{update file} \\
  \text{INOUT}[[\text{SHARE}]] \quad \text{EXCL} \quad \text{update file} \\
  \text{OUTIN} \quad \text{scratch file} \\
  \text{REL} \quad \text{release on close} \\
  \text{SAVE} \quad \text{save on close}
  \end{array}\]

The defaults for the function and disposition parameters are interrelated, as follows: for IN or INOUT files, SAVE is the default; for OUT or OUTIN files, REL is the default. (Note that for an OUT or OUTIN
The system-default value of an operational label, e.g., SI, LO, or CO, is set by the individual installation, and normally will differ from on-line to batch mode. In CP-V as distributed, the following operational labels and correspondingly named DCBs default on-line to the user's terminal: C, DO, EI, LL, LO, OC, SI, SL, and UC. Excepting the special label NO, all other operational labels have no "as-directed" default value. The operational label NO has the fixed meaning "no assignment", and while it is in force, effectively prevents any default assignment from being applied. This causes any output via a so-assigned DCB to be lost, and an immediate end-of-file return on input.

- To Clear a User-Set Assignment

  SET dcb[0]

  This form causes any prior assign/merge table entry for the named DCB to be deleted from the table. Thus, any system-default assignments are allowed to take effect in subsequent job steps.

- To Clear All User-Set Assignments

  R[RESET]

  This form deletes all previously assigned entries from the assign/merge table. All system default assignments for all standard system DCBs are in effect for subsequent steps.
GENERAL USAGE RULES

The following usage rules apply in general:

1. File or device options can be added or respecified, between job steps, for an already assigned DCB if the assignment was made by a previous SET, OUTPUT, LIST, or COMMENT command, or a processor-call parameter.

2. As stated earlier in this chapter, when assigning a file to any nonsystem-defined, loader-constructed DCB (excluding F:101, F:102, ..., F:106 for FORTRAN standard units) you must also specify one of the file-option function parameters (IN, OUT, INOUT, OUTIN), and also the disposition parameter unless the default is desired. Thus, an output-file assignment for, say, FORTRAN unit 6 would be as follows:

   \[ \text{SET } F:6 \ /OUTFIL;OUT;SAVE \]

Example 44. Setting DCB Assignments and Parameters with the SET Command

This example illustrates use of the SET command to direct input to and output from an assembly. The user obtains source output on tape, a compressed-output deck, a double-spaced output listing on the printer, and ROM output on a disk file.

\[ \text{\_SET M:SO } \text{LT\#A123-9T/Z} \leftarrow \]

This command will cause the source output from META to go to file Z on the 9-track magnetic tape having the serial number A123.

\[ \text{\_SET M:LO } \text{LO;SPACE=2} \leftarrow \]

The user wants the output listing double-spaced. Note that he must first assign M:LO. (But, see the META command below, where this assignment is changed.)

\[ \text{\_SET M:GO } /\text{BINOUT} \leftarrow \]

He wants the binary output to go to disk file BINOUT. He could alternatively have used the command:

\[ \text{\_OUTPUT ON BINOUT} \leftarrow \]

\[ \text{\_SET M:CO } P1 \leftarrow \]

This command assigns the DCB for compressed output to logical device stream P1. Utilization privilege is required when P1 is associated with the card punch (its default association).

\[ \text{\_META INFIL ON ,LP} \leftarrow \]

\[ \text{WITH>SO,CO} \leftarrow \]

The user now calls META to assemble a source file. He requests a source listing on the line printer (privilege required) and a compressed output deck.
He now calls RUN to load and execute the program.

Control returns to TEL, with no error messages having been issued.

BASIC PROCESSOR REQUIREMENTS

The BASIC processor uses the following DCBs for its I/O:

<table>
<thead>
<tr>
<th>DCB</th>
<th>Definition</th>
<th>Default Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>M:SI</td>
<td>Source input.</td>
<td>User's console (on-line job)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Card reader (batch job)</td>
</tr>
<tr>
<td>M:EI</td>
<td>Stream 1.</td>
<td>File</td>
</tr>
<tr>
<td>M:EO</td>
<td>Stream 2.</td>
<td>File</td>
</tr>
<tr>
<td>M:CO</td>
<td>Stream 3.</td>
<td>File</td>
</tr>
<tr>
<td>M:LO</td>
<td>Stream 4.</td>
<td>File</td>
</tr>
<tr>
<td>M:DO</td>
<td>Diagnostic output and output that results from a PRINT statement or a LIST</td>
<td>User's console (on-line job) Line printer (batch job)</td>
</tr>
<tr>
<td></td>
<td>command.</td>
<td></td>
</tr>
<tr>
<td>M:SO</td>
<td>Output that results from a SAVE, FILE, LOAD, RENUMBER, or CHAIN</td>
<td>File</td>
</tr>
<tr>
<td></td>
<td>command.</td>
<td></td>
</tr>
</tbody>
</table>

The assignments for any of these DCBs may be changed via the SET command. For example, the assignment for the M:DO DCB for an on-line job may be changed to line printer by the command

\[
\text{SET M:DO LP}
\]

If either the M:SI or M:DO DCB has been affected inappropriately by previous processing during the on-line session, it may be reset to the BASIC default assignment by means of the SET dcb command. Both of them may be reset at the same time via the RESET command. All other DCBs are reset to their BASIC default assignments automatically by the BASIC processor.
11. CONTROLLING OUTPUT

GENERAL

The several outputs from a compilation or assembly (or "standardized" user processor) can be selectively turned off by a DONT LIST, DONT OUTPUT, or DONT COMMENT command, either before calling a processor or during an interrupt of the processor. These specifications retain their effect across job steps, until reset or negated. Outputs may be resumed by a LIST, OUTPUT, or COMMENT command, or by specifying output destinations in a META, FORT4, or user-processor command. LIST affects the M:LO DCB, normally used for listing output; OUTPUT affects the M:GO DCB, normally used for ROM output, and COMMENT affects the M:DO DCB, normally used for diagnostic output. (M:DO cannot be affected with the META, FORT4, etc., command parameters.)

If you have assigned output to a "symbiont device", such as line printer or card punch, the output is stored on disk until you give an explicit or implicit indication that it is complete and ready to be printed or punched. You do this explicitly by issuing the TEL command PRINT, or implicitly by logging off. (Note that utilization privilege is required for these central-site units, however.)

DISCONTINUING AND RESUMING STANDARD OUTPUTS

You may interrupt META or FORT4 and turn off output by one of the following commands:

- DONT LIST turns off list output.
- DONT OUTPUT turns off binary output.
- DONT COMMENT turns off error commentary.

The DONT LIST and DONT OUTPUT commands may also be given before calling META or FORT4 if these outputs are not desired.

Output may be resumed by one of the following commands:

- LIST resumes list output as previously specified.
- OUTPUT resumes binary output as previously specified.
- COMMENT resumes error commentary as previously specified, or at the terminal by default.

Each of the above commands remains in effect during a session until you issue another command to redirect output.

The forms of these commands for explicitly directing or redirecting outputs are given in Chapter 10.

Example 45. Discontinuing and Resuming Output by OUTPUT, LIST, and COMMENT Commands

```
!BUILD INFILE ©

The user builds a source file of Meta-Symbol statements.

1,000 SYSTEM BPM ©
2,000 SYSTEM SIG7 ©
3,000 START L1,R1 1 ©
4,000 SLS,R1 24 ©
5,000 LW,R2 R1 ©
6,000 STW,R2 Y ©
```
The user specifies the destination files for binary output and object listing.

For his first assembly, he only wants to test for assembly errors, and so he turns off the OUTPUT and LIST options.

He calls META to assemble the source file.

The user notices that he forgot to define R1 and R2, and so he interrupts by depressing \( y_c \) and aborts META by typing a QUIT command.

He calls Edit to insert definitions into the source file.

He then leaves Edit.
This time he believes that the program is error-free, and so he now resets the OUTPUT and LIST options.

He now reassembles. File INFILE must be respecified since M:SI defaults to the terminal at each new job step.

PRINT COMMAND

Output directed to the symbiont output devices (card punch and printer) is normally not queued for actual output on those devices until you log off. This feature has the advantage of causing all of the output for one job to come out together.

However, you may want some of your output printed or punched immediately. The PRINT command causes your symbiont files to be closed and queued for output at once (if you have the required utilization permission).

Example 46. Causing Printer or Punch Output to be Queued by Issuing a PRINT Command

```
COPY ME TO LP

The user wants to enter lines at the terminal to be copied to the line printer.

THESE LINES ARE DIRECTED TO THE LINE PRINTER

THEY ARE NORMALLY NOT QUEUED FOR PRINTING UNTIL THE USER LOGS OFF.

THE FOLLOWING PRINT COMMAND WILL CAUSE THEM TO BE PRINTED.

The Escape F signals end-of-input.

PRINT

This command causes the line printer output to be queued immediately.

The session continues.
```
12. SAVING/RESTORING CORE IMAGES AND FILES

GENERAL

A core image of a program in process, along with relevant program context, can be saved on a disk file during an interruption of execution. You might often want to save the core image of a patched program at one or several stages of a complex debugging process, e.g., to ensure against errors in ensuing patches. The saving and reloading of core images is achieved with the ISAVE and IGET commands, shown in the first two examples to follow.

Although program-I/O file identification information is saved along with the core image, file-positioning information is not saved (and the files themselves may not be saved if closed automatically by the system). If, however, a given program is not sensitive to these considerations, then SAVE/GET can also be used as a production checkpoint-restart mechanism.

Disk (i.e., RAD or disk pack) storage is the predominant file-storage medium for the on-line user, because of the nature of remote on-line operation and the central role played by this type of storage in integrated batch/time-sharing operating systems such as CP-V. The advantages of disk storage over other types of file media were discussed briefly in Chapter 4. Disk files are, however, susceptible to loss in certain types of catastrophic system failures, or "crashes", that sometimes occur. Although the system provides extensive, automatic protection against complete file loss (as described below), generally on an "all files" basis, you can selectively create backup files anytime you feel this action is indicated. (For example, after creating an important file when working with a relatively new installation that has not yet ironed out all the wrinkles.)

Files may be saved or backed up either on the standard system save/restore magnetic tape by means of the TEL BACKUP command, or on your own private tape, pack, or on punched cards by means of the PCL COPY ALL or COPY command.

Another characteristic of disk storage is that its capacity is fixed in a sense that magnetic-tape or punched-card storage is not, and that you can easily misuse it: (1) by not promptly deleting unneeded files (you are normally charged for permanent disk space actually used, not the total extent allowed for your use), and (2) by allowing little-used files to remain on disk. You can transfer files of the latter class to tapes by the same means used to create backup copies — but do not forget to delete them from disk after verification of the copying!

SAVE AND GET COMMANDS

You can take a "checkpoint" of a core image at some desired point by interrupting the execution and issuing a SAVE command. The core image of the program and other information that enables the system to reconstruct the program's environment (other than I/O-file positioning) are then saved on disk. After you issue the SAVE command, the interrupted program can be resumed by a GO or CONTINUE command.

Later you can restore the checkpointed program to core by issuing a GET command. Following the GET command by a GO or CONTINUE command causes processing to be resumed at the point at which the checkpoint was taken.

In the next example, we assemble a program with META but discover coding errors when it does not execute properly. Instead of editing the source file and reassembling, we choose to enter patches with DELTA (see Chapter 7). To preserve a patched version of the program, we interrupt prior to execution and issue a SAVE command. The patched version is restored by a GET command in Example 48 and executed again.

Example 47. Saving a Core Image of a Program (SAVE Command)

```
.

BUILD INPUT

1.000 SYSTEM BPM

2.000 SYSTEM SIG7
```
The user assembles the program, and asks for symbolic debugging code to be produced.

* NO UNDEFINED SYMBOLS
* ERROR SEVERITY LEVEL: 0
* NO ERROR LINES

LINKING BO

REGISTERS NOT PRESERVED IN SUBR

The program error message prints.

SAVE and GET Commands 93
RUN BO UNDER DELTA

The user now runs under Delta because he wants to add patches to the program before executing again.

LINKING BO

DELTA HERE
"RING"

The Delta debugging processor identifies itself and prompts with a bell.

BO;S

The user identifies the symbol table associated with the ROM (BO).

EXIT+20\ STW,1 EXIT+19
EXIT+15\ LI,1 100
EXIT+16\ BDR,1 $
EXIT+17\ LW,1 EXIT+19
EXIT+18\ B *EXIT
SUBR\ B EXIT+20

He enters patches into the program (see Example 33 for meaning of these commands).

Y^C+

He depresses CONTROL and Y after the prompt to interrupt Delta. The system echoes a left arrow.

SAVE MYJOB

He issues a SAVE command to save the patched program on file MYJOB.

GO

The GO command takes him back to Delta.

START;G

He issues a Delta command to start execution of the program. (No prompt is given.)

EXIT AT RETURN + .9

Delta prints this message on execution of an M:EXIT.

Y^C+

The user now leaves Delta.
Example 48. Restoring a Checkpointed Program (GET Command)

```plaintext
GET MYJOB @

The user restores the checkpointed core image (the patched program on file MYJOB). This file was created by the SAVE command in Example 47.

GO @

The GO command causes a return to Delta, the processor that was interrupted to perform the SAVE.

START;G @

The user initiates execution. (No prompt is given for this line.)

EXIT AT RETURN + .9

The program completes execution.
```

BACKUP COMMAND

The BACKUP command provides a means of creating backup files. Files are copied to the standard system backup tape. Note that the usage of BACKUP may be subject to rules and restrictions conditioned by specific installation practices concerning the saving/restoring of files.

A keyed file called MAILBOX in the user's account will contain completion messages resulting from the backup process.

The next example illustrates use of the BACKUP command. This example also shows that we must wait for the backup process to complete before finding out what is in the MAILBOX file.

Example 49. Saving a File on the Standard System Backup Tape

```plaintext
BUILD MYFILE @

The user builds file MYFILE.

BACKUP MYFILE @

He issues a BACKUP command to copy the file on the system backup tape.

COPY MAILBOX @

300 FILE DOES NOT EXIST.

He wants to see what is in the MAILBOX file, but this file does not yet exist because the backup process is not complete.

COPY MAILBOX @

He waits a minute or so for the backup process to complete then issues the COPY command again.

16:18 MAY 25, '71 BY ABGD ON SN45AL BACKED UP FILE MYFILE

The completion message in file MAILBOX now prints.
```
COPYALL AND COPY COMMANDS

SAVING ON TAPE

Many times you will want to save one, several, or all of your files on magnetic tape, in addition to those implied by the "proper usage" guideline offered near the beginning of this chapter. For instance, if you were going on an extended vacation, you might want to copy all your disk files to tape and thus save disk storage charges. Or, if you are making many versions of a file, perhaps many assemblies, you may want to back up the original file on tape. In the next example, the user transfers all the files in his account to tape and pulls them off as needed in the session. He also transfers a single, additional file to the tape. The example shows the use of CP-V labeled tape rather than free-form tape. Using labeled tape, the user can request his files by name from the tape, as he would call them by name from his disk directory. With free-form tape, he would have to know the ordinal positions of the files on the tape, and space forward or backward the appropriate number of files before he could read or write the files he wanted. (This example is illustrative of what can be done, but not necessarily of what may normally be done, since it implies usage of a central-site resource in a manner that may or may not be allowed in a given installation.) Note that copying one file or the entire account to tape does not automatically delete the file(s) from disk; disk files must be explicitly deleted by command. Also, tape files are no longer "in the system." That is, the system "knows" only of files in the user's account on disk; the user is responsible for knowing the tape's label or number, and for notifying the central-site operator of the same (see Chapter 14).

Remember that any utilization of magnetic tape, as well as any other central-site resource, requires a prior permission by the installation.

See the CP-V/TS Reference Manual, 90 09 07, Chapter 5, for a description of the Rewind (REW) and Space-to-EOT (SPE) commands shown in the next example.

Example 50. Transfer of All Files in User's Account to Labeled Tape

```
::
_1PCL @
PCL D00 HERE
<LIST @
ARCSINE
DATAFIL
JOBFIL
ROMFIL
SOURCE
VPRIME

The user lists the names of the files in his disk account.

<REW #3B96 @
He rewinds the tape (#3B96) he is going to write on, to be certain it is positioned to start of tape. This assumes, of course, that the tape has been mounted at the computer site. See Chapter 14 on user-operator communication. If the tape already contained files he wanted to keep, he would instead want to skip to the position following the last file on the tape by issuing the command <SPE LT#3B96.

<COPYALL TO LT#3B96 @
He copies all the files in his account, in succession, to labeled tape (LT) #3B96.

<REW #3B96 @
He rewinds tape #3B96 that he has just written on before listing it. He visually compares the list with the one he received when he listed the disk directory.
```
The user creates a new file from the terminal.

He spaces labeled tape #3B96 to the mark following the last file on the tape.

He adds file NEW to labeled tape #3B96.

He rewinds tape #3B96 and lists the names of its files. PCL has successfully added file NEW after the last file written to tape, VPRIME.

Satisfied that his files are safely stored on tape, he now deletes all files in his disk account. PCL requires a "YES$" verification of the DELETEALL request, and upon its receipt, PCL deletes all of the user's files and so notifies him.
The user wishes to use file NEW as input to a processor later in the session. He calls it from the tape back to his account with a new name, INPUT.

He issues the REMOVE command, which rewinds the tape and automatically issues a "dismount" message to the control-site operator.
13. SUBMITTING BATCH JOBS

BATCH COMMAND

The BATCH command is used to submit a batch job deck stored on a file to the batch input stream. This job deck must include all appropriate batch control cards that would be needed for normal batch job submission.

Example 51. Submitting a Job via BATCH Subsystem for Execution

```
1.000 SYSTEM SIG7
2.000 SYSTEM BPM
3.000 REF M:LO
4.000 START M:WRITE M:LO,(BUF,MES),(SIZE,9)
5.000 M:EXIT
6.000 ERROR THIS LINE CONTAINS AN ERROR
7.000 MES TEXT 'IT WORKS.'
8.000 END START
9.000

The user builds a source program that he wishes to assemble in the batch environment.
```

```
1.000 JOB
2.000 IASSIGN M:SI, (FILE, BATCHIN)
3.000 IASSIGN M:BO, (FILE, BINARY)
4.000 IASSIGN M:DO, (FILE, ERRORS)
5.000 IMETASYM SI, BO, LO
6.000

He builds a file containing a batch job-control deck that will assemble the file called BATCHIN.
```

```
1.000 SUBMIT JOBA
```

```
13:13 MAY 26, '71
ID=0028 SUBMITTED
```

He submits the batch job he has just created. The job identification (ID) prints as a hexadecimal value. Note that the JOB command did not specify an account, user name, or priority. When these parameters are omitted, they are supplied by the system and default to the logged-on account, user name, and the highest priority authorized that user.
CANCEL COMMAND

If the user wishes to cancel a job previously submitted by the BATCH command, he may do so by using the CANCEL command.

\[ \text{CANCEL jid} \]

where jid is the job identification that printed just after the job was submitted.

JOB COMMAND

The JOB command is used to ask for the status of a batch job. The system responds that the job is either completed, running, or still waiting to be run. The format of the command is

\[ \text{JOB jid} \]

where jid is the job identification that printed just after the job was submitted.

Example 52. Using the JOB Command

```
: : 
JOB 28 ☞
The user requests the status of the job submitted in the previous example. The job identification 0028 is the same as the one reported when the job was submitted using the BATCH command.

WAITING: 1 TO RUN
The system answers that there is one batch still to be run before this job is run.
: 
JOB 28 ☞
Later the user asks again.

COMPLETED
Now the job is complete.

COPY ERRORS ON ME ☞
The user displays the diagnostics from the job at the terminal. Note that M:DO was assigned to file ERRORS in the job-deck JOBA.

6 ERROR THIS LINE CONTAINS AN ERROR

```
14. COMMUNICATION WITH THE OPERATOR

MESSAGE COMMAND

The MESSAGE command causes a message to be sent to the central-site computer operator. The message may be from 1 to 72 characters in length.

The format of the command is

:\!MESSAGE message-text

If the message-text exceeds 44 characters, the first 44 characters are printed on one line at the operator's console and the remaining characters are printed on a second line.

In the next example, the user informs the operator that he needs a scratch tape.

Example 53. Sending a Message to the Operator

\:.\:
\:.\!MESSAGE READY SCRATCH TAPE TO BECOME 9055. @

The user sends a message to the computer operator requesting that he be ready to mount a scratch tape.

\:.\!BUILD DATAPoints @

He builds file DATAPoints.

\:.\:
\:.\!COPY DATAPoints TO PT9055 @

He requests that the file to be copied to a free-form tape with the serial number 9055. The system informs the operator where to mount the requested scratch tape.

MESSAGES FROM THE OPERATOR

The computer operator can send a message to an individual terminal or broadcast a message to all users. When he broadcasts a message, the message is placed into the right-hand part of the page title for the terminals and it will be seen by a user when he receives a new page heading. A message sent to an individual terminal may appear anywhere in the user's output.

Note: If the PLATEN command was used to turn page headings off, the broadcast message will not appear.

In the next example, the user receives a message informing him that the system will soon go off. He issues a BACKUP command before logging off to insure that his latest files will be saved. This action may not really be necessary, depending on installation practice; the system normally will save all files automatically before going off.

Example 54. Receiving a Message from the Operator

\:.\:
\:.\!BUILD XYZ @

The user builds a source file.
He wants to continue file building (or processing) on a new page, so he simultaneously depresses CONTROL and L to cause a page eject.

(page eject)

23:45 05/26/71 JONES ABC 1BB-F[17] CP-V WILL GO OFF AT 2400

Included as part of the page heading is the message from the operator CP-V WILL GO OFF AT 2400. This message has been sent to all users.

OFF

The user decides to terminate his processing at this time, and he uses a BACKUP command to save his last file.

OFF

Messages from the Operator
APPENDIX A. TEL COMMAND SUMMARY

Table A-1 is a summary of TEL commands. The first column gives the command format, the second column gives the command's function and option codes. For the structure of file names (fid, rom, lmn) see Table B-1.

Table A-1. TEL Command Summary

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKUP fid</td>
<td>Saves the specified file on a system tape. In case of a crash in which files are lost, files on the tape will be restored.</td>
</tr>
<tr>
<td>BATCH fid[,fid]... (Simplified format)</td>
<td>Enters the specified file(s) in the batch job stream.</td>
</tr>
<tr>
<td>B[UILD] fid</td>
<td>Allows a new file to be created from the terminal using the Edit processor.</td>
</tr>
<tr>
<td>BYE</td>
<td>Disconnects the terminal from the system and provides an accounting summary. This command is equivalent to the OFF command.</td>
</tr>
<tr>
<td>CANCEL jid[,jid]...</td>
<td>Cancels previously submitted batch jobs.</td>
</tr>
</tbody>
</table>
| COBOL[sp] [ON] [OVER [rom][,list]] | Compiles an ANS COBOL source program.  
Options:  
sp may be fid or ME.  
rom may be fid, stream-id, CP, or NO.  
list may be fid, stream-id, LP, ME, or NO.  
Output may be interrupted and continued by the following commands:  
LIST DONT LIST DONT COMMENT  
OUTPUT DONT OUTPUT CONTINUE  
COMMENT |
| COMMENT[ON list] | Directs error commentary to the specified device, or counteracts the preceding DONT COMMENT command. Option: list may be fid, LP, ME, or stream-id. |
| CONTINUE | Continues processing from the point of interruption. This command is equivalent to the GO and PROCEED commands. |
| COPY sf [TO†] df [OVER] | Copies a file or device input to the specified file or device.  
Options:  
sf may be fid or device code.  
df may be fid or device code.  
†Whenever TO is specified, ON may be substituted.

<tr>
<td>JOB jid[,jid]..</td>
<td>Requests the status of jobs that were submitted to the batch queue via the Batch processor.</td>
</tr>
</tbody>
</table>

\[LT# reel-id [-rt][s]]
\[DC][acct][s]]
LT# serial no. [-rt][s]/fid[s][, fid[s]]
L fid[s][, fid[s]]
DP# serial no. [-rt]/fid[s][, fid[s]]
FT# serial no. [-rt][s]]

Lists file names and, optionally, attributes from the account directory, tape, or disk pack.

Options:
- s may be A or EA.
- rt specifies the 2-character identifier of a device that was defined at SYSGEN to be a resource.

LDEV stream-id[, (option)]...

Modifies a logical device definition.

LINK [options]rom[,rom ...][ON OVER lmn]

Forms the load modules as specified.

Options:
- library search: (L), (NL), (Pl), (JI), (FDP), (NP)
- default: (L), (Pl)
- display: (D), (ND), (C), (NC), (M), (NM)
- default: (D), (C), (NM)
- symbol tables: (I), (NI)
- default: (I)
- execute accounts: (EX, acct[,acct]...)

rom may be fid or $; parentheses enclosing roms cause merge of symbol tables.

lid must name a file containing one or more roms.

LIST [ON OVER list]

Directs the listing output to the specified device, or counteracts the preceding DONT LIST command.

Option: list may be fid, LP, ME, or stream-id.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `Lmn[sp]ON [rom][,list]` | Initiates execution of a load module. Options:  
`Lmn` has the form:  
```plaintext
name[,account][,password]
```
- absence of period and account specifies system account,  
- presence of period and absence of account specifies log-on account.  
- `sp` is assigned to `M:SI DCB`.  
- `rom` is assigned to `M:GO DCB`.  
- `list` is assigned to `M:LO DCB`. |
| `MESSAGE` text | Sends the specified message to the operator. The first character of the message may not be a period (.) |
| `META[sp]ON [rom][,list]` | Assembles the specified Meta-Symbol source program. Options:  
- `sp` may be `fid` or `ME`.  
- `rom` may be `fid`, `stream-id`, `CP`, or `NO`.  
- `list` may be `fid`, `stream-id`, `LP`, `ME`, or `NO`.  
Output may be interrupted and continued by the following commands:  
```plaintext
LIST DONT LIST DONT COMMENT
OUTPUT DONT OUTPUT CONTINUE
COMMENT
```
| OFF | Disconnects the terminal from the system and provides an accounting summary. This command is equivalent to the `BYE` command. |
| OUTPUT `ON fid` | Directs object output to the specified file, or counteracts the previous `DONT OUTPUT` command. |
| PAGE n | Resets the terminal header page number to the value specified by n. |
| `PASSWORD, old-password, new-password`  
`PASSWORD, new-password`  
`PASSWORD, old-password`, | Assigns, changes, or deletes a log-on password for the user. The password is 1-8 characters and cannot contain  
`1, ;<>./=?`  
and all COC control characters. A null field is used to specify non-existence of either an old or new password. |
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLATEN[w][l]</td>
<td>Sets the value of the terminal platen width and/or page length if w and/or l are specified; or displays the terminal platen width and page length values if neither w nor l is specified. (Page length does not include header.)</td>
</tr>
<tr>
<td>PRINT</td>
<td>Sends accumulated symbiont output, such as output for the line printer or the card punch, to the output device.</td>
</tr>
<tr>
<td>PROCEED</td>
<td>Continues processing from the point of interruption. This command is equivalent to the GO and CONTINUE commands.</td>
</tr>
<tr>
<td>Processor Calls</td>
<td>These calls are entered while TEL is in control of the terminal. They turn over control of the terminal to the processor. Examples are:</td>
</tr>
<tr>
<td>QUIT</td>
<td>Terminates the current job step. This command is equivalent to the STOP and END commands.</td>
</tr>
<tr>
<td>RESET</td>
<td>Resets all DCBs back to their system default values.</td>
</tr>
<tr>
<td>RESTORE fid</td>
<td>Restores the previously saved core image. This command is equivalent to the GET command.</td>
</tr>
<tr>
<td>RUN [options][rom[rom]...][ON] OVER [mn] [lid[lid]...] UNDER DELTA FDP</td>
<td>Loads the specified module and starts execution. Options:</td>
</tr>
<tr>
<td>SAVE [ON] OVER fid</td>
<td>Saves the current core image on the designated file.</td>
</tr>
<tr>
<td>SEND</td>
<td>Allows messages from the machine operator to be printed on the user's terminal.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| SET dcb[0] | Assigns file or device to a DCB or sets DCB parameter. Options:  
  - rt is the 2-character identifier of a device that was defined at SYSGEN to be a resource.  
  - other options, see Tables C-1 through C-4. |
| SET dcb [ device ] | SET dcb [ stream-id ]  
  [tapecode[rt]]  
  [filecode[-rt]]  
  [fid[fpopt]]...  
  SET dcb JR/fid | Displays information about currently logged-on user. Options: USER, PRIV, DCBS, M:xx or F:xx, or ALL. |
| SHOW [option[,option]...] | Loads a load module into core and starts execution of the program, either with or without an associated debugger. |
| START[ UNDER DELTA] | Displays the current accounting values. |
| STOP | Terminates the current job step. This command is equivalent to the END and QUIT commands. |
| SWITCH [SET = n[,n]...[RESET = n[,n]...]] | Controls setting and resetting of the user's pseudo sense switches, where n ranges from 1 to 6. With no arguments the command displays the pseudo sense switch settings. This command is the equivalent of the batch ISWITCH command. |
| TABS [s[,s]... ] | Sets simulated tab stops for the terminal if s values are specified; or displays the simulated tab stop settings if no s value is specified. |
| TERMINAL[ ] | SET(type[,algorithm]) | Sets the terminal type for proper I/O translations. Type may be 33, 35, 37, 7015, DATA[POINT], EAPL, ESTD, EXEC[PORT], MEMO[REX], SAPL, SSTD, or TI. Algorithm may be 0-7. |
| TERMINAL STAT[US] | Lists the terminal type and the current values of parameters associated with its operation. |
| TP | This command logs off a time-sharing terminal and makes it available as a slave Transaction Processing terminal. |
| U | Causes the words UNDER DELTA to be inferred in the next command. |
| WHERE account, name | Returns the line number of the specified user (if the user is logged on). |
APPENDIX B. FILE IDENTIFIERS AND THEIR PARTS

A file identification (fid) consists of a file name and optionally an account and/or a password. Special types of files are an Imn (load module) which is produced as a result of a LINK or RUN command, and a rom (relocatable object module) which is produced by an assembler or compiler. Table B-1 illustrates the structure of a fid.

Table B-1. File Identifiers and Their Parts

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Imn</td>
<td>a file identifier (fid) that names a load module.</td>
</tr>
<tr>
<td>rom</td>
<td>a file identifier (fid) that names a relocatable object module.</td>
</tr>
<tr>
<td>fid</td>
<td>name [, account] [, password]</td>
</tr>
<tr>
<td>name</td>
<td>1 to 12 characters of the X character set.</td>
</tr>
<tr>
<td>account</td>
<td>1 to 8 characters of the X character set.</td>
</tr>
<tr>
<td>password</td>
<td>1 to 8 characters; the following characters may not be used: 1, ; &lt; &gt; . / = ? and all control characters acted upon by the COC.</td>
</tr>
<tr>
<td>X character set</td>
<td>A-Z a-z 0-9 _ — $ * % : @ -</td>
</tr>
</tbody>
</table>

The usage "name." is valid only when the fid is an Imn used as a command verb (see Chapter 8).
APPENDIX C. SET COMMAND CODES

Tables C-1 through C-4 define the codes which may be used as options in the SET command.

### Table C-1. DCB Assignment Codes – SET Command

<table>
<thead>

<tr>
<td></td>
<td>(and others defined at SYSGEN)</td>
<td></td>
</tr>
<tr>
<td>Logical Device Stream</td>
<td>L1</td>
<td>Line printer.</td>
</tr>
<tr>
<td></td>
<td>C1</td>
<td>Card reader.</td>
</tr>
<tr>
<td></td>
<td>P1</td>
<td>Card punch.</td>
</tr>
<tr>
<td></td>
<td>(and others defined at SYSGEN)</td>
<td></td>
</tr>
<tr>
<td>Magnetic Tape (tapecode)</td>
<td>LT</td>
<td>Xerox labeled tape.</td>
</tr>
<tr>
<td></td>
<td>AT</td>
<td>ANS labeled tape.</td>
</tr>
<tr>
<td></td>
<td>FT</td>
<td>Free form tape.</td>
</tr>
<tr>
<td>Secondary Storage (filecode)</td>
<td>DP</td>
<td>Disk pack storage.</td>
</tr>
</tbody>
</table>

### Table C-2. Device Options – SET Command

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASC[II]</td>
<td>ASC[II] specifies code conversion (between ASCII on tape and EBCDIC in core). EBCDIC is assumed by default and ASCII is legal only for tapes having this feature.</td>
</tr>
<tr>
<td>BCD, BIN</td>
<td>Controls the binary-BCD mode for device read and write operations. BIN used in conjunction with DRC will invoke the transparent mode. (See Transparent Mode section of Chapter 11.)</td>
</tr>
<tr>
<td>COUNT = value</td>
<td>Turns on page counting and specifies the column number at which the page number is to be printed.</td>
</tr>
<tr>
<td>DATA = value</td>
<td>Controls the beginning column for printing or punching and is a decimal value. The maximum value is 144.</td>
</tr>
<tr>
<td>DEN= {800}</td>
<td>Specifies the density that will be used on a dual density tape device.</td>
</tr>
<tr>
<td>DEN= {1600}</td>
<td></td>
</tr>
</tbody>
</table>
### Table C-2. Device Options - SET Command (cont.)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DRC, NODRC</td>
<td>Turns the special formatting of records on and off. DRC specifies that the monitor is not to do special formatting of records on read or write operations. NODRC specifies the monitor is to do special formatting. If neither DRC nor NODRC is specified, NODRC is assumed by default. DRC used in conjunction with BIN will invoke the transparent mode. (See Transparent Mode section of Chapter 11.)</td>
</tr>
<tr>
<td>FBCD, NOFBCD</td>
<td>Controls the automatic conversion between external Hollerith code and internal EBCDIC code (FORTRAN BCD conversion). NOFBCD is assumed by default.</td>
</tr>
<tr>
<td>IN</td>
<td>Specifies the input mode.</td>
</tr>
<tr>
<td>OUT</td>
<td>Specifies the output mode.</td>
</tr>
<tr>
<td>INOUT</td>
<td>Specifies the input and output mode (i.e., the update mode).</td>
</tr>
<tr>
<td>OUTIN</td>
<td>Specifies the output and input mode (i.e., the scratch mode).</td>
</tr>
<tr>
<td>L, NOL</td>
<td>Identifies the device type. L specifies that the device must be listing type, NOL specifies that it need not be listing type. NOL is assumed by default.</td>
</tr>
<tr>
<td>LINES = value</td>
<td>Specifies the number of printable lines per page and is a single decimal value. The maximum value is 255.</td>
</tr>
<tr>
<td>PACK, UNPACK</td>
<td>Controls the packed or unpacked mode of writing 7-track tape. PACK is assumed by default.</td>
</tr>
<tr>
<td>RECL = value</td>
<td>Specifies the default record length, in bytes. The greatest value that may be specified is 32,767. If RECL is not specified, a standard value (appropriate to the type of device used) will apply. The value specified in a SET command will override that assembled into the DCB but will not override the RECL specification of an M:OPEN call or the SIZE specification of an M:READ or M:WRITE procedure call.</td>
</tr>
<tr>
<td>SEQ [= value]</td>
<td>Specifies that sequence numbers are to be punched in columns 77-80 of punched output. Four characters of nonblank sequence identification may be given for columns 73-76. Fewer than 4 characters are left-justified and blank filled.</td>
</tr>
<tr>
<td>SN [= value]</td>
<td>Specifies the serial numbers of volumes that are to be used for input or output. The serial number may be from 1 to 4 characters except for ANS labeled tape serial numbers which must be 6 characters. A maximum of 3 serial numbers may be specified. If a serial number is specified with the tapeid, it is included in the 3 allowed. An existing list of serial numbers may be removed by specifying the SN option with no arguments.</td>
</tr>
<tr>
<td>SPACE = value</td>
<td>Specifies the number of lines of space after printing and is a single decimal value. Values of 0 or 1 result in single spacing. The maximum value is 255.</td>
</tr>
<tr>
<td>TAB = tab[, tab ...]</td>
<td>Specifies simulated tab stops and is followed by a list of up to 16 decimal numbers, separated by commas, giving the column position of the stops. If all 16 stops are not specified, the stops given are assigned to the first stops and the remainder are reset.</td>
</tr>
<tr>
<td>TRIES = value</td>
<td>Specifies the maximum number of recovery tries to be performed for any I/O operation. The greatest value that may be specified is 255. The default value is 10.</td>
</tr>
<tr>
<td>VFC, NOVFC</td>
<td>Controls the formatting of printing by using the first character of each record. VFC specifies that the first character of each record is a format-control character. NOVFC specifies that records do not contain a format-control character. NOVFC is assumed by default.</td>
</tr>
<tr>
<td>Type</td>

Table C-3. File Options – SET Command (cont.)

<table>
<thead>
<tr>
<th>Type</th>
<th>Format</th>
<th>Disk</th>
<th>Xerox Tape</th>
<th>ANS Tape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Structure</td>
<td>NEWX=slides [...]</td>
<td>X</td>
<td></td>
<td></td>
<td>The &quot;slides&quot; argument specifies the number of blocks that can be added to the file's index since the current higher-level index structure was built; if the specified value is exceeded, the higher-level index structure will be rebuilt when the file is closed. If a value of 255 is specified, the higher-level index structure will not be built (or rebuilt). If NEWX is not specified, the value 254 is used in default.</td>
</tr>
<tr>
<td></td>
<td>[..., consecutive slides]</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Execute Accounts</td>
<td>EX[ECUTE] acct [..., acct]</td>
<td>X</td>
<td></td>
<td></td>
<td>Specifies the account numbers of the accounts that may execute the load module. A maximum of 8 accounts may be specified. The value ALL may be used to specify that any account may execute the file. The value NONE may be used to specify that no other account may execute the file. In all of the above cases, READ, NONE is implied in the absence of any READ specification. This option with no arguments resets all previous execute account entries in the DCB.</td>
</tr>
<tr>
<td></td>
<td>[ALL, NONE]</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Read Accounts</td>
<td>READ acct [..., acct]</td>
<td>X</td>
<td>X</td>
<td></td>
<td>Specifies the account number of those accounts that may read but not write the file. This option is applicable to OUT and OUTIN files. A maximum of 8 read accounts may be specified. The value ALL may be used to specify that any account may read the file. The value NONE may be used to specify that no other account may read the file. This option with no arguments resets all previous read account entries,</td>

<tr>
<td>Write Accounts</td>
<td>WR[ITE] [acct[, acct]... ]</td>
<td>X</td>
<td>X</td>
<td></td>
<td>Specifies the account numbers of those accounts that may have both read and write access to the file. This option is applicable to OUT and OUTIN files. A maximum of 8 write accounts may be specified. The value ALL may be used to specify that any account may have write access to the file. The value NONE may be used to specify that no other account may have write access to the file. This option with no arguments resets all previous write account entries.</td>
</tr>
<tr>
<td>Volume Serial</td>
<td>SN[=value[, value][, value]]</td>
<td>X</td>
<td>X</td>
<td>X</td>
<td>Specifies the serial number of volumes that are to be used for input or output. The serial number may be from 1 to 4 characters, except for ANS labeled tape serial numbers which must be 6 characters. A maximum of 3 serial numbers may be specified. If serial number is specified with tapeid, it is included in the 3 allowed. An existing list of serial numbers may be removed by specifying the SN option with no arguments.</td>
</tr>
<tr>
<td>Code Conversion</td>
<td>ASC[II] EBC[DIC]</td>
<td>X</td>
<td>X</td>
<td></td>
<td>ASCII specifies code conversion between ASCII on tape and EBCDIC in core. EBCDIC specifies no code conversion. EBCDIC is the default. ASCII is legal only for tapes having the code conversion feature.</td>
</tr>
<tr>
<td>Recording Density</td>
<td>DEN= [800] [1600]</td>
<td>X</td>
<td>X</td>
<td></td>
<td>Specifies the density that will be used on the dual density tape device.</td>
</tr>
<tr>
<td>Initial Volume</td>
<td>VOL=value</td>
<td>X</td>
<td>X</td>
<td></td>
<td>Specifies which tape reel in the SN list is to be used initially. A value of 1 designates the first, a value of 2 the second, etc. If VOL is omitted, a value of 1 is assumed.</td>
</tr>
<tr>
<td>Concatenate Tape</td>
<td>[CON]CAT=value</td>
<td></td>
<td></td>
<td>X</td>
<td>Specifies the number of identically named files that are to be read as one logical file (concatenated). The value may be in the range of 2 through 255.</td>
</tr>
<tr>
<td>Tape Format</td>
<td>{FORMAT} =character</td>
<td></td>
<td></td>
<td>X</td>
<td>Specifies the record format. The character may be: F = fixed length; D = variable specified in decimal; V = variable specified in binary; or U = undefined.</td>
</tr>
</tbody>
</table>
### Table C-3. File Options – SET Command (cont.)

</table>

*These device assignments are standard in CP-V but may be changed at SYSGEN.*
APPENDIX D. LINK AND RUN COMMANDS CODES

Tables D-1 through D-4 define the codes that may be used in the LINK and RUN commands.

### Table D-1. Library Search Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(L)</td>
<td>Specifies that the system library is to be searched to satisfy external references that have not been satisfied by the program. (This is the default option.)</td>
</tr>
<tr>
<td>(NL)</td>
<td>Specifies that a system library search is not required.</td>
</tr>
<tr>
<td>(Pi) or (Ji)</td>
<td>Specifies that the ith public core library is to be searched for unsatisfied external references. Default is to Pi if no other public core library is specified. Only one public library of each type (J and P) may be associated with a program.</td>
</tr>
<tr>
<td>(FDP) or (P0)</td>
<td>Specifies that the FORTRAN Subprogram Library P0, that includes the Debug routines, is required.</td>
</tr>
<tr>
<td>(NP)</td>
<td>Specifies that a public core library is not required.</td>
</tr>
</tbody>
</table>

**Note:** The sequence of the library search is as follows: User libraries are searched first, the public library is associated, then the system library is searched.

### Table D-2. Error Displays

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(D)</td>
<td>Specifies that all unsatisfied internal and external symbols are to be displayed at the completion of the linking process (including library searches, if specified). The unsatisfied symbols are identified as to whether they are internal or external and to which module they belong.</td>
</tr>
<tr>
<td>(ND)</td>
<td>Specifies that the unsatisfied internal and external symbols are not to be displayed.</td>
</tr>
<tr>
<td>(C)</td>
<td>Specifies that all conflicting internal and external symbols are to be displayed. The symbols are displayed with their source (module name) and type (internal or external).</td>
</tr>
<tr>
<td>(NC)</td>
<td>Specifies that the conflicting symbols are not to be displayed.</td>
</tr>
<tr>
<td>(M)</td>
<td>Specifies that the load map is to be displayed upon completion of the linking process. The symbols are displayed by source with type resolution and value.</td>
</tr>
<tr>
<td>(NM)</td>
<td>Specifies that the load map is not to be displayed.</td>
</tr>
</tbody>
</table>

**Note:** The normal default options are D, C, and NM.
### Table D-3. Symbol Table

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(I)</td>
<td>Specifies that internal symbols of the next module specified are to be included in the load module. (This is the default option.)</td>
</tr>
<tr>
<td>(NI)</td>
<td>Specifies that internal symbols of the next module specified are not to be included in the load module.</td>
</tr>
</tbody>
</table>

### Table D-4. Execution

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(EX, acct[, acct]...)</td>
<td>Specifies those accounts which may execute this load module. Up to 8 accounts may be specified. The value ALL may be used to specify that any account may execute the load module. The value NONE may be used to specify that no other account may execute the load module.</td>
</tr>
</tbody>
</table>
APPENDIX E. SPECIAL TERMINAL KEYS

Certain terminal keys, key sequences, and key combinations cause action to be taken other than simple transmission of the character. Table E-1 illustrates these key sequences and the action produced.

<table>
<thead>
<tr>
<th>Key Sequence</th>
<th>Action Produced</th>
</tr>
</thead>
<tbody>
<tr>
<td>@E</td>
<td>Sets or resets the flag that controls the echo and no-echo modes.</td>
</tr>
<tr>
<td>@F</td>
<td>Causes end-of-file action on input.</td>
</tr>
<tr>
<td>I or IC</td>
<td>Functions as a tab key.</td>
</tr>
<tr>
<td>@L or Lc</td>
<td>Causes spacing to a new page and printing of new page heading.</td>
</tr>
<tr>
<td>@O or @OQ</td>
<td>Simulates a local line feed. No activation occurs.</td>
</tr>
<tr>
<td>@S</td>
<td>Sets or resets the flag that controls space-insertion mode.</td>
</tr>
<tr>
<td>@T</td>
<td>Sets or resets the flag that controls tab simulation.</td>

APPENDIX F. USE OF THE 2741 TERMINAL

This appendix is intended for the person who would like to use the CP-V Time-Sharing User's Guide, but can not because his terminal is a 2741 terminal or a terminal that is designed to operate like a 2741. Not all features of the 2741 are discussed – only those that are needed to do the examples in the User's Guide. For a more detailed discussion of the differences between the 2741 and Teletype terminals, see the CP-V/TS Reference Manual, 90 09 07.

It is recommended that you do each of the examples in this appendix at your terminal to be sure that you understand them. Then turn back to the front of this User's Guide. When doing the examples, use the 2741 equivalent where needed instead of the Teletype entry. Differences between Teletype and 2741 control characters are summarized in the CP-V/TS Reference Manual, 90 09 07.

CONTROL CHARACTERS

All time-sharing terminal devices have at least one key on their keyboard that allows them to send special control messages to the Monitor. These messages are called control characters. On the 2741 terminal, most control characters are sent by first pressing an alphabetic key and then pressing the ATTN key. The Monitor signals the user that it has received the control character by backspacing and underscoring the letter he typed. It then performs whatever function the user has asked for.

For the remainder of this appendix, the sending of a control character will be described by specifying the letter, followed by the symbol that represents the ATTN key (\(\text{\texttt{\(\text{ATTN}\)}}\)). For example, the user may request that his current line of input be retyped by entering the letter r, followed by ATTN. This is presented here as the r\(\text{\texttt{\(\text{ATTN}\)}}\) sequence.

Table F-1 summarizes the differences between 2741 terminals and Teletype terminals. You will find this table helpful throughout the manual. As you encounter each Teletype control character in the text, you will be able to choose the appropriate 2741 equivalent.

LOGGING ON

To log on to CP-V on a 2741 terminal, you must first dial the phone and place the handset in the audio-coupling device. When you have established contact with the computer (in most cases, this is signaled by the unlocking of the keyboard) you must identify your terminal’s specific character set by typing an asterisk, followed by a carriage return. CP-V will then be able to communicate meaningfully with your terminal. CP-V responds to your terminal identification with a request for you to log on.

* @

XEROX CP-V AT YOUR SERVICE
ON AT 22:29 SEP 26, '72
LOGON PLEASE: 1234, JONES @

Note that Jones was typed with all uppercase letters. This is required unless you inform the system that you wish all alphabetic characters to be treated as uppercase. The exclamation point indicates that your log-on has been accepted and the system is now ready to accept TEL commands.
SUPPRESSING LOWERCASE LETTERS

There are many cases where lowercase letters will not be accepted in lieu of uppercase letters. The log-on sequence described above is one example. If lowercase letters are used when logging on, an error message is output. To avoid this problem the user must either remember to use uppercase letters when required or enter the u sequence, which suppresses the lowercase letter capability and causes the system to treat all letters as if they were uppercase.

* "*

XEROX CP-V AT YOUR SERVICE
ON AT 22:57 SEP 26, '72
LOGON PLEASE: 1234 ,jones @
ACCOUNT/ID 1234/jones?
LOGON PLEASE: u1234 ,jones @
1
In this example, the user forgot to use uppercase letters when he logged on. The system responded with an error message and asked the user once again to log on. This time the user entered the \texttt{u} \texttt{~} \texttt{sequence}, requesting that all letters typed be accepted as uppercase letters. He then reentered his account and id, and it didn’t matter whether he used uppercase or lowercase letters. If he wished to use lowercase letters later in the session, he could reset the lowercase suppression by entering another \texttt{u} \texttt{~} \texttt{sequence}.

The \texttt{u} \texttt{~} \texttt{sequence} was entered by typing the letter \texttt{u}, and then pressing the ATTN key. The system acknowledged receipt of the sequence by backspacing and underscoring the \texttt{u}.

\textbf{CORRECTING TYPING ERRORS}

Each character that you type while logged on to CP-V is sent when you press the key. However, in most cases CP-V simply stores what you type until you press the carriage return. At that point, the entire line of information is processed. As a result, corrections can easily be made at any point in a line of input prior to pressing the carriage return.

The backspace \texttt{~} \texttt{sequence} most often is used to make single corrections to typing errors. To correct the last character typed, press the backspace key, then the ATTN key. The letter you now type will replace the letter that you are typing over.

```
\_build sample \texttt{~}
  1,000 oooooo \texttt{~}
  2,000 \texttt{~}
\_copy sample \texttt{~}
  000001
```

In this example, a file name "sample" is created using the TEL BUILD command. The file contains one record, and was typed originally as six letter \texttt{o}'s. A backspace \texttt{~} \texttt{sequence} was entered, and the last \texttt{o} replaced with an \texttt{i}. When the TEL COPY command was used to copy the file to the terminal, the file was printed in all uppercase letters. This happened because we had used the \texttt{u} \texttt{~} \texttt{sequence} earlier to cause all letters to be treated as uppercase. If you wish to delete more than one character, simply enter the backspace \texttt{~} \texttt{sequence} once for each character to be deleted.

```
\_build samplel \texttt{~}
  1,000 ooooooo \texttt{~}
  2,000 \texttt{~}
\_copy samplel \texttt{~}
  0000111
```

In this example, six letter \texttt{o}'s were entered in the only record of a file named "sample1". Before entering a carriage return, however, three successive backspace \texttt{~} \texttt{sequences} were entered. Three letter \texttt{i}'s were then typed to replace the deleted characters. Again when the file was output at the terminal by the TEL COPY command, all uppercase letters were typed since the earlier \texttt{u} \texttt{~} \texttt{sequence} was still in effect.

```
\_build newfile \texttt{~}
  1,000 ooooooo \texttt{~}
  2,000 \texttt{~}
\_copy newfile \texttt{~}
  00111
```

\textbf{Appendix F} 116
At this point, a lowercase sequence was entered so that typed lowercase letters would no longer be converted to uppercase. As a result, the TEL BUILD command had to be typed in uppercase. Also, it is important to note that the name of this file is “newfile” and that it can only be referred to in lowercase letters. In the only record in this file, six letter a’s were typed, then four backspace sequences were entered. Two uppercase I’s were typed, followed by a space, one lowercase i, and a carriage return. The result was a record containing o0ll i.

**USING TABULATION**

The TAB key on the 2741 terminal operates in the same way as the TAB key on a standard typewriter. Each time the TAB key is pressed, the carrier moves to the next tab stop. The place where the carrier stops is determined by the physical tab setting on the machine itself. In addition to this typical typewriter feature, the 2741 also sends a tab character to CP-V each time the TAB key is pressed. When information is being typed from a file, a tab character causes the carrier to move to the next tab stop on the machine just as pressing the TAB key would do.

```
!build sample3
1,000 one two three four
2,000
!copy sample3
ONE TWO THREE FOUR
```

In this example, a file named “sample3” is created. The physical tabs on the terminal were set to every five positions (i.e., 5, 10, ...). The file was then copied back to the terminal. If we change the physical tab stops on the terminal to every fifteen positions (i.e., 15, 30, ...) and copied the file again, the following would result:

```
!copy sample3
ONE TWO THREE FOUR
```

In this example, the file named “sample3” was copied to a 2741 terminal with physical tab settings at every fifteenth position.

The TEL TABS command is used to inform the system of the tab settings that the user has at his terminal. If you plan to use tab settings, you should inform CP-V of the settings you plan to use.

```
!TABS 5,10,45
```

In this example, tab settings of 5, 10, and 45 were specified for this terminal. If you wish to specify or change tab settings, enter them any time that the system prints an exclamation point at your terminal.

CORRECTIONS TO XEROX CONTROL PROGRAM-FIVE (CP-V)/TIME-SHARING
USER’S GUIDE (Sigma 6/7/9 Computers)

PUBLICATION NO. 90 16 92D, JUNE, 1973

The attached pages contain changes for the B00 version of CP-V. Pages in the D edition of the manual that are to be replaced are: 1, 2, 5, 6, 9, 10, 29-32, 45, 46, 49-52, 65, 66, 85-88, and 101-112. New pages to be inserted are: 10-1, 31-1, and 107-1.

These changes will be incorporated into the next edition of the manual.

Revision bars in the margins of replacement pages identify changes. Pages without the publication number 90 16 92D-1(2/74) at the bottom are included only as backup pages; revision bars appearing on such pages identify changes made in a previous revision.

CORRECTIONS TO XEROX CONTROL PROGRAM–FIVE (CP-V)/TIME-SHARING USER'S GUIDE
(Xerox 560 and Sigma 6/7/9 Computers)

PUBLICATION NO. 90 16 92D, JUNE, 1973

The attached pages contain changes for the COO version of CP-V. Pages in the D edition of the manual with revised pages labeled 90 16 92D-1(2/74) that are to be replaced are: front cover, title page, ii, v, vi, 1, 2, 5, 6, 9, 10, 85-88, 107, 109, and 110. New pages to be inserted are: 107-1, 109-1, and 110-1 through 110-4.

These changes, as well as those contained on pages labeled 90 16 92D-1(2/74), will be incorporated into the next edition of the manual.

Vertical bars in the outer margins of replacement pages indicate portions (one or more lines) of text changed to reflect COO version of CP-V. Vertical bars on pages not labeled 90 16 92D-2(10/74) indicate portions of text changed by previous revisions.
CORRECTIONS TO CP-V/TIME-SHARING USER'S GUIDE

PUBLICATION NO. 90 16 92D

The attached pages contain changes that reflect the C01 version of Control Program-Five (CP-V). Pages in the D edition of the manual (which has previously been revised by the D-1 and D-2 revision packages) that are to be replaced are: i, ii, 10-1, 105 through 109-1, and 110-1 through 112. A new page to be inserted is 112-1.

These changes will be incorporated in the next edition of the manual.

Revision bars in the margins of replacement pages identify changes. Pages without the publication number 90 16 92D-3(5/75) at the bottom are included only as backup pages; revision bars appearing on such pages identify changes made in a previous revision.
CORRECTIONS TO XEROX CP-V/TIME-SHARING USER'S GUIDE (Xerox 560 and Sigma 6/7/9 Computers)

PUBLICATION NO. 90 16 92D, NOVEMBER 1971

The attached pages contain changes for the D00 version of CP-V. Pages in the D edition of the manual with revision pages labeled 90 16 92D-1(2/74), 90 16 92D-2(10/74), and 90 16 92D-3(5/75) that are to be replaced are: title page ii, 1, 2, 5-8, 103-107, 107-1, 109, 109-1, 110-3, 110-4, and 111-116. A new page to be inserted is 115-1.

These changes, as well as those contained in previous revision packages, will be incorporated into the next edition of the manual.

Vertical bars in the outer margins of replacement pages labeled 90 16 92D-4(12/75) indicate portions of text changed to reflect the D00 version of CP-V. Vertical bars on other pages indicate text changed as the result of previous revisions.
